Joint Beacon Power and Beacon Rate Control Based on Game Theoretic Approach in Vehicular Ad Hoc Networks

Hamid Garmani, Driss Ait Omar, Mohamed El Amrani, Mohamed Baslam, and Mostafa Jourhmane

Abstract—In vehicular ad hoc networks (VANETs), each vehicle broadcasts its information periodically in its beacons to create awareness for surrounding vehicles aware of their presence. But, the wireless channel is congested by the increase beacons number, packet collision lost a lot of beacons. This paper tackles the problem of joint beaconing power and a beaconing rate in VANETs. A joint utility-based beacon power and beacon rate game are formulated as a non-cooperative game and a cooperative game. A three distributed and iterative algorithm (Nash Seeking Algorithm, Best Response Algorithm, Cooperative Bargaining Algorithm) for computing the desired equilibrium is introduced, where the optimal values of each vehicle beaconing power and beaconing rate are simultaneously updated at the same step. Extensive simulations show the convergence of a proposed algorithm to the equilibrium and give some insights on how the game parameters may vary the game outcome. It is demonstrated that the Cooperative Bargaining Algorithm is a fast algorithm that converges the equilibrium.

Index Terms—Beacon rate, Beacon power, Non-cooperative game, Cooperative game, VANETs, Game theory, Nash equilibrium, Nash bargaining solution.

I. INTRODUCTION

VANETs is a new paradigm of wireless communications that aim to exploit the recent advances in wireless devices technology to enable intelligent inter-vehicle communication. The appearance of VANETs has been becoming an interesting field for the traffic research community during the last decades. VANETs provides a new trend for Intelligent Transportation Systems such as public transport management [1], and improve security in transportation to reduce the number of disasters. Various types of safety have been designed for VANETs, including emergency alert, accident notification, curve alert, file-sharing, internet, and advertisements.

Several work used game theory in wireless networks [3] [4] [5] [6] [7] [8]. The authors in [9] proposed a beacon power control algorithm; every player calculates the maximum beaconing power to achieve the maximum communication power and keeps the Channel Busy Ratio (CBR) under a threshold. In [10], the authors study the performance of a multi-hop broadcast protocol in VNET's safety by designing a generic probabilistic forwarding scheme and proposing an analytical model to study the performance of the proposed model. The authors in [11] provide a mechanism to find the optimal beacon rates founded on the maximization of the utility function and show the impact of the beacon rate on the performance of the network. In [12], the authors studied a dynamic congestion control mechanism as a means of broadcasting BSM, and to guarantee the reliable and timely delivery of messages to all vehicles.
neighbors in a network. The authors in [13] used the tabu search algorithm with multi-channel allocation capability to reduce the time delay and jitter for improving the quality of service in VANET. In [10], the authors proposed a vehicle mobility prediction founded beacon rate adaptation approach, where each vehicle uses the prediction module to get the situation of their neighbors in real-time. The authors in [14] studied the competition among vehicles in beaconing power as a non-cooperative game. In [15] the authors used the non-cooperative game for designing a beacon rate control mechanism. The authors proved the uniqueness of the Nash equilibrium point and proposed a distributed method is used to find the equilibrium point. In this paper, we utilize a non-cooperative game and the cooperative game to study the joint control beaconing rate and beaconing power in VANETs. We propose three algorithms for learning joint beaconing rate and beaconing power at Nash equilibrium and Nash bargaining solution.

In this paper, a fair and stable joint beaconing power and beaconing rate problem in VANETs are formulated and solved based on the non-cooperative games and cooperative game. The incentive and objective of the proposed approach are finding the vehicle beaconing power and beaconing rate in a distributed manner to decrease the number of losses of beacons. The theory of supermodular games and the Nash bargaining solution are used to solve the corresponding optimization problem. We prove the existence of the Nash equilibrium point in the non-cooperative game. Furthermore, we implement three learning algorithms that find the equilibrium point in a distributed manner by adjusting beaconing rates and beaconing powers jointly in a single step. Performance evaluation shows the convergence of the proposed algorithm to the equilibrium beaconing power and the beaconing equilibrium rate, and show the impact of system parameters on vehicle strategies. Also, it is revealed that the proposed cooperative game algorithm is the best choice for the vehicle to control the beaconing rate and beaconing power.

The rest of this paper is organized as follows. In Section II, we describe the proposed model. In Section III, we present the non-cooperative game formulation and the price of anarchy. In Section IV, we present a cooperative game. Then, we present the Performance evaluation in Section V. Finally, in Section VI conclusions.

II. SYSTEM MODEL

The utility function of each vehicle is the difference between revenue and fees. Accordingly, the payoff of the vehicle $i$ can be written as:

$$U_i = a_i \log(r_i + p_i + 1) - c_i \rho_i CBR_i(p_i, r_i, p_{-i}, r_{-i}) - (C_{s_i} + C_{t_i} p_i + C_{r_i} r_i)$$

where $a_i$ and $c_i$ are two positive parameters. $CBR_i(p_i, r_i, p_{-i}, r_{-i})$ is the channel busy ratio that vehicle $i$ senses, and it is a function of all vehicle beaconing rates and beaconing power, where $p_i = (p_1, p_{-i}, p_1, p_{-2}, \ldots, p_N)$. The term $a_i \log(r_i + p_i + 1)$ is the revenue of vehicle $i$; it is an increasing function with respect to beaconing rate and beaconing power. A logarithmic function has been used because it is increasing and has excellent concavity properties. Thus, the vehicle with lower beaconing power and their beaconing rate has more incentive to increase their beaconing power and their beaconing rate. The second term $c_i \rho_i CBR_i(p_i, r_i, p_{-i}, r_{-i})$, is the congestion cost. It indicates that a vehicle should pay higher costs at higher congestions, which discourages the vehicles from using a high beacon rate and high beacon power. The third term $C_{s_i} + C_{t_i} p_i + C_{r_i} r_i$ is the energy consumed to send beacons and to switch the state of the transceiver. $C_{s_i}$ is the energy consumed for switching the state of the transceiver, $C_{t_i}$ is the energy consumed for sending beacons with power $p_i$, and $C_{r_i}$ is the energy consumed for sending beacons with a rate $r_i$.

Then, we define $CBR_i(p_i, r_i, p_{-i}, r_{-i})$ as that in [16] by

$$CBR_i(p_i, r_i, p_{-i}, r_{-i}) = \sum_{j=1}^{N} h_{ij} r_j$$

where

$$h_{ij} = T_{frame} \times \frac{\Gamma(m, \frac{C_{t_i} p_i}{\gamma})}{\Gamma(m)}$$

and

$$\Omega_{ij} = \frac{\rho_i \lambda^2}{(4\pi\gamma)^2 d_{ij}^4}$$

$\Gamma$ is the gamma function, $\Gamma(\ldots, \ldots)$ is the upper incomplete gamma function, $C_{t_i}$ is the threshold power level of carrier sense, $p_j$ is the BSM transmit power of vehicle $j$, $d_{ij}$ is the distance between $j$th and $i$th vehicles, $m$ is Nakagami fading parameter, $\lambda$ is the wavelength, $\gamma$ is the path loss exponent, $r_j$ is the beaconing rate of vehicles $j$, and $T_{frame}$ is the time needed to transmit a beacon message.

Equation (2) indicates that the channel load experienced by vehicle $i$ is the weighted sum of the beaconing rate of all the other vehicles $\sum_{j=1}^{N} h_{ij} r_j$. The channel load also depends on various parameters such as channel fading, the time needed to transmit a beacon message, and the distance of other vehicles. The coefficients $h_{ij}$ defined in (3), represents the action of these parameters in the channel load sensed by vehicle $i$.

III. A NON-COOPERATIVE GAME FORMULATION

Let $G = [\mathcal{N}, (R_i, P_i), (U_i(.)]$, denote the non-cooperative beaconing rate and beaconing power game (NRPG), where $\mathcal{N} = \{1, \ldots, N\}$ is the index set identifying the vehicle $i$, $R_i$ is the beaconing power strategy set of vehicle $i$, $P_i$ is the beaconing rate strategy set of vehicle $i$, and $U_i(.)$ is the utility function of vehicle $i$ defined in Equation (1). We assume that the strategy spaces $R_i$ and $P_i$ of each vehicle $i$ are compact and convex sets with maximum and minimum constraints, for any given vehicle $i$ we consider as strategy spaces the closed intervals $R_i = [R_{iL}, R_{iU}]$ and $P_i = [P_{iL}, P_{iU}]$. Let the beaconing power vector $p = (p_1, \ldots, p_N)^T \in \mathbb{R}^N = R_1 \times R_2 \times \ldots \times R_N$, beaconing rate vector $r = (r_1, \ldots, r_N)^T \in \mathbb{R}^N = R_1 \times R_2 \times \ldots \times R_N$. 

MARCH 2021 • VOLUME XIII • NUMBER 1

Joint Beacon Power and Beacon Rate Control Based on Game Theoretic Approach in Vehicular Ad Hoc Networks
Definition 1 The strategy vector \((p^*, r^*) = (p_1^*, p_2^*, ..., p_N^*, r_1^*, r_2^*, ..., r_N^*)\) is a Nash equilibrium of the NRPG \(G = [\mathcal{N}, \{R_i, P_i\}, \{U_i(\cdot, \cdot)\}]\) if
\[
\forall (i, R_i, P_i) \in [\mathcal{N}, R_i, P_i], \quad U_i(p_i, r_i) \geq U_i(p_i, r_i^*) \geq U_i(p_i^*, r_i) \geq U_i(p_i^*, r_i^*)
\]

Theorem 5 The unique Nash equilibrium point of the NRPG \(G\) is given by:
\[
(p^*_i, r^*_i) = \arg \max_{p_i \in P_i, r_i \in R_i} U_i(p, r)
\]
dependent payoffs for continuous actions. Algorithm 1
summarizes the best response learning steps that each player
has to perform to discover its Nash equilibrium strategy.

Nash seeking algorithm is one of the most known learning
schemes. It is a discrete-time learning algorithm, using sinus
perturbation, for continuous action games where each vehicle
has only a numerical realization of the payoff at each time. At
each iteration $t$, the vehicle $i$ chooses its beaconing power and
beaconing rate and obtains from the environment the realization
of its payoff. The improvement of the strategy is based on the
current observation of the realized payoff and previously
chosen strategies. Hence, we say vehicles learn to play an
equilibrium, if after a given number of iterations, the strategy
profile converges to an equilibrium strategy. The proposed
learning framework has the following parameters: $\phi_i$ and $\phi'_i$
are the perturbation phase, $z_i$ and $z'_i$ are the growth rate, $b_i$
and $b'_i$ are the perturbation amplitude, and $\Omega_i$ and $\Omega'_i$
are the perturbation frequency. This procedure is repeated for the
window $T$. Algorithm 2 summarizes the Nash seeking
algorithm learning steps that vehicle $i$ has to perform in order
to discover its Nash equilibrium beaconing power and
beaconing rate.

Algorithm 1 Best Response Algorithm
1: Initialize vectors $p(0) = [p_1(0), ..., p_N(0)]$ and $r(0) = [r_1(0), ..., r_N(0)]$ randomly;
2: For each vehicle $i$ at round $t$ computes:
   - $p_i(t + 1) = \text{argmax}(U_i(p_i, r))$.
   - $r_i(t + 1) = \text{argmax}(U_i(p_i, r))$.
3: If $|p_i(t + 1) - p_i(t)| < \epsilon$ and $|r_i(t + 1) - r_i(t)| < \epsilon$, then STOP.
4: Else make $t \leftarrow t + 1$ and go to step (2).

Algorithm 2 Nash Seeking Algorithm
1: Data:
   - $\phi_i \in [0, 2\pi]$ and $\phi'_i \in [0, 2\pi]$: perturbation phase;
   - $b_i > 0$, $b'_i > 0$: perturbation amplitude;
   - $\Omega_i$, $\Omega'_i$: perturbation phase;
   - $z_i$, $z'_i$: the growth rate;
2: Initialization:
3: Assign a value for $r_{t0}^i$, $\phi_{t0}^i$, $p_{t0}^i$, and $r_{t0}^i = i, 1, 2, ..., N$;
4: Learning pattern: For each iteration $t$:
6: Observes the payoff $U_{it}$ and estimates $\phi_{t+1}$ and $\phi'_{t+1}$ using
   - $\phi_{t+1} = \phi_t + t \cdot z_i \cdot b_i \sin(\Omega_i t^*) + \phi_t$)
   - $\phi'_{t+1} = \phi'_t + t \cdot z'_i \cdot b'_i \sin(\Omega'_i t^*) + \phi'_t$)
7: Update beaconing rate $r_i$ and beaconing power $p_i$ using the following rules
   - $p_{t+1} = p_t + b_i \sin(\Omega_i t^* + \phi_t)$;
   - $r_{t+1} = r_t + b'_i \sin(\Omega'_i t^* + \phi'_t)$;

B. Price of Anarchy
The price of anarchy (PoA) is defined as the ratio between the
performance measures of the worst equilibrium and the optimal
outcome. A PoA close to 1 indicates that the equilibrium is
approximately socially optimal, and thus the consequences of
selfish behavior are relatively benign.

In [17], we measure the loss of efficiency due to actors’
selfishness as the quotient between the social welfare obtained
at the Nash equilibrium and the maximum value of the social
welfare:

$$\text{PoA} = \frac{\min_{\{p,r\}} W_N(p,r)}{\max_{\{p,r\}} W(p,r)} \quad (29)$$

where $W(p,r) = \sum_{i=1}^N U_i(p,r)$ is the social welfare function
and $W_N(p^*,r^*) = \sum_{i=1}^N U_i(p^*,r^*)$ is a sum of utilities of all
players at Nash Equilibrium.

IV. COOPERATIVE GAME
The Nash bargaining game [18] is a cooperative game in which
players have a mutual agreement for cooperation in order to
obtain a higher payoff compared to the non-cooperative case.
Let $U$ be a closed and convex subset of $\mathbb{R}^N$ that represents
the set of feasible payoff allocations that the players can get if they
all cooperate. Suppose $\{U_i \in U | U_i \geq U_i^{\text{min}}, \forall i \in N\}$ is
a nonempty bounded set. Define $U^{\text{min}} = (U_1^{\text{min}}, U_2^{\text{min}}, ..., U_N^{\text{min}})$, then the pair of $(U, U^{\text{min}})$ constructs a
$K$-player bargaining game. Here, we define the Pareto
efficient point [19], where a player can not find another point
that improves the utility of all the players at the same time.

Definition 3 A strategy profile $(p^*, r^*) = (p_1^*, p_2^*, ..., p_N^*, r_1^*, r_2^*, ..., r_N^*)$ is
Pareto-optimal if and only if there is no other strategy profile $(p, r)$ such that $U_i(p, r) \geq U_i(p^*, r^*)$, $\forall i \in N$, and
$U_i(p^*, r^*) > U_i(p^*, r^*)$, $\exists i \in N$, i.e., there exists no other strategies that lead to superior
performance for some players without causing inferior performance
for some other players [19].

There may be an infinite number of Pareto optimal points in a
game of multi-players. Thus, we must address how to select a
Pareto point for a cooperative bargaining game. We need a
criterion to select the best Pareto point of the system. A possible
criterion is the fairness of resource allocation. Notably, the
fairness of bargaining games is a Nash bargaining solution,
which can provide a unique and fair Pareto optimal point under
the following axioms.

Definition 4 $\overline{T}$ is a Nash bargaining solution in $U$ for $U^{\text{min}}$
i.e., $\overline{T} = \mathcal{H}(U, U^{\text{min}})$, if the following axioms are satisfied [19]:
   - Individual rationality: $T_i \geq U_i^{\text{min}}$, $T_i \in \overline{T}$, $i \in N$.
   - Feasibility: $\overline{T} \in U$.
   - Pareto Optimality: $T$ is Pareto optimal.
   - Independence of Irrelevant Alternatives: If $\overline{T} \in \mathcal{U} \subset U$, $\overline{T} = \mathcal{H}(\mathcal{U}, U^{\text{min}})$, then $\overline{T} = \mathcal{H}(U, U^{\text{min}})$.
   - Independence of Linear Transformations: For any linear scale transformation $\theta$, $\theta(\mathcal{H}(U, U^{\text{min}})) = \mathcal{H}(\theta(U), \theta(U^{\text{min}}))$.
   - Symmetry: If $U$ is invariant under all exchanges of

MARCH 2021 • VOLUME XIII • NUMBER 1

INFOCOMMUNICATIONS JOURNAL
Theorem 6 A unique and fair Nash bargaining solution \( x^* = (p^*, r^*) \) that satisfies all the axioms in Definition 4 can be obtained by maximizing a product term as follows:

\[
x^* = \arg\max_{p \in P, r \in R} \prod_{i=1}^N U_i(p, r)
\]

Proof: The proof of the theorem 6 is omitted due to space limitations. A similarly detailed proof can be found in [18].

Our work aims to maximize utility functions while decreasing the number of losses beacons. Therefore, the corresponding cooperative Nash bargaining game-theoretic power and rate control problem for vehicle underlying the communication system can be formulated as:

\[
P1: \max_{p \in P, r \in R} \prod_{i=1}^N U_i(p, r)
\]  

s.t.  

\[
\begin{align*}
(C1) & : 0 \leq p_i \leq p_i^{max} \\
(C2) & : 0 \leq r_i \leq r_i^{max}
\end{align*}
\]

where constraint C1 limits the beaconing power of vehicle \( i \) to be below \( p_i^{max} \) and C2 limits the beaconing rate of vehicle \( i \) to be below \( r_i^{max} \).

Lemma 1 Define \( V_i(p, r) = \ln(U_i(p, r)) \), \( i \in N \). These objective functions are concave and injective, which satisfy all the Nash axioms in Definition 4.

Proof: The proof of theorem 5 shows that the Hessian matrix of the utility function \( U_i(p, r) \) is negatively definite. Then, the utility function \( U_i(p, r) \) is strictly concave with regard to the 2-tuple \( (p_i, r_i) \). Subsequently, \( V_i(p, r) = \ln(U_i(p, r)) \) is also concave in \( (p_i, r_i) \). Therefore, \( V_i(p, r) \) defined above satisfies all the axioms defined by Theorem 4 and Theorem 6.

According to Theorem 6 and Lemma 1, the unique Nash bargaining equilibrium with fairness can be found over the strategy space. Then, taking advantage of the increasing property of the logarithmic function, the optimization problem P1 can be rewritten as:

\[
P2: \max_{p \in P, r \in R} \sum_{i=1}^N V_i(p, r) = \max_{p \in P, r \in R} \sum_{i=1}^N U_i(p, r)
\]  

s.t.  

\[
\begin{align*}
(C1) & : 0 \leq p_i \leq p_i^{max} \\
(C2) & : 0 \leq r_i \leq r_i^{max}
\end{align*}
\]

A. Solution of the Cooperative Game

Herein, we derive the unique equilibrium by solving the constrained optimization problem in (20) utilizing the method of Lagrange multipliers [20]. Introducing Lagrange multipliers \( \{x_i\}^N_{i=1} \) and \( \{\psi_i\}^N_{i=1} \) for the multiple constraints, the Lagrangian of problem (20) can equivalently be solved by maximizing the following expression:

\[
\mathcal{F}(p, r; \{x_i\}^N_{i=1}, \{\psi_i\}^N_{i=1}) = \sum_{i=1}^N \left( a_i \log(r_i + p_i + 1) - c_i p_i CBR(p, r) - C_p r_i - x_i p_i - \psi_i r_i \right)
\]

Based on the standard optimization methods and the Karush–Kuhn–Tucker conditions, the beaconing power of vehicle \( i \) can be obtained by taking the first derivative of (21) with respect to \( p_i \), which is expressed as follows:

\[
\frac{\partial \mathcal{F}}{\partial p_i} = \frac{a_i}{1 + p_i + r_i} - c_i CBR(p, r) - C_p - x_i
\]

Letting \( \frac{\partial \mathcal{F}}{\partial p_i} = 0 \) we get,

\[
p_i^* = \frac{a_i}{c_i CBR(p, r) + C_p + x_i} - 1 - r_i^*
\]

Meanwhile, the beaconing rate of vehicle \( i \) can be obtained by taking the first derivative of (21) with respect to \( r_i \) as

\[
\frac{\partial \mathcal{F}}{\partial r_i} = \frac{a_i}{1 + p_i + r_i} - c_i h_i - C_r_i - \psi_i
\]

Let (24) equals to zero, then we get

\[
r_i^* = \frac{a_i}{c_i h_i + C_r_i + \psi_i} - 1 - p_i^*
\]

In this work, we employ the fixed-point technique to derive an iterative procedure that updates the beaconing rate and beaconing power control decisions, which can be given as:

\[
p_i^{(t+1)} = \frac{a_i}{c_i CBR(p, r) + C_p + x_i^{(t)} + 1} - 1 - r_i^{(t)}
\]

\[
r_i^{(t+1)} = \frac{a_i}{c_i h_i + C_r_i + \psi_i^{(t)} + 1} - 1 - p_i^{(t)}
\]

B. Update of the Lagrange Multipliers

The Lagrange multipliers \( \{x_i\}^N_{i=1} \) and \( \{\psi_i\}^N_{i=1} \) need to be updated to guarantee the fast convergence property. Several practical approaches can be employed in the update of Lagrange multipliers. In this paper, the sub-gradient technique is utilized to update the multipliers, as formulated as follows:

\[
\begin{align*}
\psi_i^{(t+1)} &= \psi_i^{(t)} - \beta \frac{\partial \mathcal{F}}{\partial \psi_i^{(t)}} \\
x_i^{(t+1)} &= x_i^{(t)} - \beta \frac{\partial \mathcal{F}}{\partial x_i^{(t)}}
\end{align*}
\]

where \( (x)^+ = \max(0, x) \), \( \beta \) denotes the step size of iteration \( t \) \((t \in \{1, 2, \ldots, L_{max}\}) \). \( L_{max} \) denotes the maximum number of iterations.

C. Iterative Nash Bargaining Algorithm

In this section, a distributed algorithm is proposed as an implementation of our cooperative bargaining beaconing rate and beaconing power control solution. The proposed iterative Algorithm 3 will guarantee convergence by using the subgradient method.

Algorithm 3 Cooperative Bargaining Algorithm

1: Initialize \( c, a, C, C_p, h, r, \) and Lagrange multipliers \( \{x_i\}^N_{i=1} \) and \( \{\psi_i\}^N_{i=1} \); set \( t = 1 \);  
2: Initialize \( \{p_i^{(t)}\}^N_{i=1} \) and \( \{r_i^{(t)}\}^N_{i=1} \);  
3: repeat
4: for \( t = 1 \) to \( N \) do  
5: (i) Update \( p_i^{(t)} \) according to (26);  
6: (ii) Update \( r_i^{(t)} \) according to (27);  
7: (iii) Update \( x_i^{(t)} \) and \( \psi_i^{(t)} \) according to (28);  
8: end for  
9: for \( t = 1 \) to \( N \) do  
10: (i) Set \( t = t + 1 \);  
11: until Convergence or \( t = L_{max} \)  
12: return \( \{p_i^{(t)}\}^N_{i=1} \) and \( \{r_i^{(t)}\}^N_{i=1} \).
V. PERFORMANCE EVALUATION

Extensive experiments have been conducted toward investigating the following issues: (1) what is the number of iterations required by the proposed algorithm to converge toward the equilibrium beaconing rate and equilibrium beaconing power; (2) what is the fast algorithm that converges toward the equilibrium strategies; (3) In what way could system parameters affect the beaconing equilibrium rate and the equilibrium beaconing power? In this section, we demonstrate these experimental results by considering the previous expressions of the utility function. As an illustration, we consider a scenario with two vehicles.
Joint Beacon Power and Beacon Rate Control Based on Game Theoretic Approach in Vehicular Ad Hoc Networks

The uniqueness of the joint beaconing rate and beaconing power at Nash equilibrium is demonstrated in Figures 1, 2, 3, and 4. The best response algorithm and Nash seeking algorithm converges to the values of the beaconing rate and beaconing power at Nash equilibrium. Furthermore, based on the results presented in figure 1, 2, 3, 4, 5, and 6 we observe that the convergence of the proposed algorithms is very fast, Nash seeking algorithm converges within approximately 43 iterations, the best response algorithm needs five to 35 iterations to converge, while the cooperative bargaining algorithm converges after 10 iterations to the Pareto-optimal equilibrium. Then, the cooperative bargaining algorithm is the algorithm that converges very fast to the equilibrium; thus, it can be easily adopted in a realistic scenario.

Note that for any vehicle $i$, its Nash equilibrium beaconing rate $r_i$ and beaconing power $p_i$ primarily depends on the parameter $a_i$, $c_i$, $C_p$, and $C_r$. As such, we investigate how the Nash equilibrium points can be affected by these parameters.

Figures 7 and 8 show the beaconing rate and beaconing power of the vehicle when the parameter $a$ increases from 1 to 20. The beaconing rate and beaconing power of the vehicle increase with the increase of the parameter $a$. The reason is that as the parameter $a$ increases, the utility increases. Therefore, the vehicles are more incentive to increase their beaconing rate and beaconing power. Greater parameter $a$ leads to the use of higher beaconing rate and beaconing power by vehicles because of the utility function increases.

Figures 6, 7, and 8 illustrate the beaconing rate and beaconing power at Nash equilibrium using a cooperative bargaining algorithm.
We plot in Figures 9 and 10, respectively, the interplay of cost \( c \) the beaconing rate and beaconing power, for both vehicles that we consider in this example. On the one hand, we note that the beaconing equilibrium rate and beaconing power for both vehicles is decreasing with respect to the cost \( c \). When the cost \( c \) increases, the vehicles pay more price at higher congestions, yielding a lower payoff. Therefore, the vehicles need to decrease their beaconing rate and beaconing power to decrease the congestion cost. In addition, the Nash bargaining solution beaconing strategy are lower than the non-cooperative beaconing strategy, which indicates that the Nash bargaining solution is more efficient in terms of congestion cost. Therefore, cooperation is the best choice for the vehicle.

Figures 11 and 12 show both the beaconing power and the beaconing for the non-cooperative games and the cooperative strategic beaconing obtained using the Nash bargaining solution. When energy cost \( (C_r \text{ and } C_p) \) increases, the beaconing power, and beaconing rate decreases, it can be seen that the Nash bargaining solution beaconing strategy exhibits low as the energy cost level increases compared to the non-cooperative beaconing strategy. A unique feature is that the strategic beaconing scheme based on the Nash bargaining solution performs better in terms of energy compared to the non-cooperative strategy for all the values of energy cost. Therefore, the Nash bargaining solution scheme guarantees a higher network lifetime compared to a non-cooperative policy.

Figure 13 shows the PoA variation curve as a function of the parameter \( c \). PoA decreases with respect to \( c \). When \( c \) is lower, the price of anarchy is socially efficient; moreover, when \( c \) is lower, the vehicles cooperate for optimizing the Nash equilibrium. On the other hand, when \( c \) increase the PoA is lower, then the Nash equilibrium is not socially efficient, vehicles are selfish, and each one seeks to maximize its profit individually.

Fig. 10. Beaconing rate with respect to \( c \).

Fig. 11. Beaconing power with respect to \( C_p \).

Fig. 12. Beaconing rate with respect to \( C_r \).

Fig. 13. Price of Anarchy as a function of parameter \( c \).
Figure 14 shows PoA variation curve as a function of parameter $a$. In that figure, PoA increases with respect to the parameter $a$. When the parameter $a$ is lower, the price of anarchy is lower. Then, the Nash equilibrium is not socially efficient, the vehicles are selfish, and each one seeks to maximize its profit individually. However, when the parameter $a$ increases, the equilibrium becomes more and more socially efficient, this increase finds the simple intuition that when parameter $a$ increases vehicles cooperate with each other for optimizing Nash equilibrium.

VI. CONCLUSION

In this paper, the problem of joint beaconing rate and beaconing power control in VANETs is addressed via S-modular theory. The competition between the vehicle in VNETs is formulated as a non-cooperative game and a cooperative game, where each vehicle chooses the joint beaconing rate and beaconing power. We have performed the equilibrium analysis and proposed a three distributed algorithm for computing the equilibrium point. Simulation results illustrate the impacts of the system parameters on the joint beaconing rate and beaconing power and show the number of iteration required by each algorithm for the convergence to the equilibrium. The analysis and simulation results provide a better understanding of the complex interactions among vehicles under a competitive and cooperative condition, which is a benefit for the optimization of vehicle strategies.

Driss Ait Omar received the Ph.D. degrees from University Sultan Moulay Slimane, Morocco, in 2019. His research interests include network economics, applications of game theory in wireless networks, network security.

Mohamed El Amrani is a PhD student at the Faculty of Sciences and Technology, University Sultan Moulay Slimane, Morocco. His research interests include network economics, network security, applications of game theory in wireless networks, and radio resource management.

Mohamed Baslam is a Professor of computer science in the Faculty of Sciences and Technology, Sultan Moulay Slimane University, Morocco. His current research interests include performance evaluation and optimization of networks based on game-theoretic and queuing models, applications in communication/transportation and social networks, such as wireless flexible networks, bio-inspired and self-organizing networks, and economic models of the Internet and yield management.

Mostafa Jourhmane is a professor of mathematics and computer science in the Faculty of Sciences and Technology, Sultan Moulay Slimane University, Morocco. His research interests include Numerical analysis, classification, image processing, neural networks, big data, Network Engineering Games, social networks and their control and the analysis through game theoretical models of network and neutrality issues.
