Abstract

We give an algorithm to compute the integer cohomology groups of any real partial flag manifold, by computing the incidence coefficients of the Schubert cells. For even flag manifolds we determine the integer cohomology groups, by proving that any torsion class has order 2 (generalizing a result of Ehresmann). We conjecture that this holds for any real flag manifold. We obtain results concerning which Schubert varieties represent integer cohomology classes, their structure constants and how to express them in terms of characteristic classes. For even flag manifolds and Grassmannians we also describe Schubert calculus. The Schubert calculus can be used to obtain lower bounds for certain real enumerative geometry problems (Schubert problems).

1 Introduction

In this paper we study the integer and rational coefficient cohomology of real partial flag manifolds.

1.1 Additive structure

1.1.1 Incidence coefficients

Complex flag manifolds have cell decompositions into even dimensional (complex) cells which makes the computation of CW-cohomology easy: all boundary maps are trivial. The generators of the cohomology groups can be represented by Schubert

varieties whose multiplicative structure constants are given by Schubert calculus which is a classical and well-developed theory [36].

Real flag manifolds also have a cell decomposition, however the boundary maps are no longer trivial. The boundary maps have been first examined by Ehresmann [16]: he computed them completely for the case of real Grassmannians $Gr_p(\mathbb{R}^{p+q}) = Fl_{p,q}^{\mathbb{R}}$ [16, p. 80], [13, p. 73], up to sign for flag manifolds of type $Fl_{p,q,r}^{\mathbb{R}}$ [16, p. 85] and he determined the cycles in the case of $Fl_{1,q,r}^{\mathbb{R}}$ [16, p. 87]. In the case of Grassmannians, Pontryagin [44, Theorem 1] determined which Schubert varieties are cycles with rational coefficients (with some restrictions), see also [23, III.3.2.2.B] and [20]. Ehresmann also observed that the incidence coefficients are 0 or ± 2 . This implies that the mod 2 cohomology groups of flag manifolds have an additive basis given by the Schubert cycles. Their mod 2 multiplicative structure constants follow from a theorem of Borel and Haefliger [7]: they agree with the structure constants of the complex Schubert cycles mod 2.

More generally, R -spaces (the flag manifolds of real semisimple Lie groups) have Bruhat cell decompositions [15]. If all multiplicities of the restricted roots are greater than 1, then there are no cells of neighboring dimensions [15]. In this case, the boundary relations of this cell decomposition are trivial, so additively the cohomology groups are freely generated by the closures of the Bruhat cells. If the multiplicities are not such, the boundary relations are no longer trivial, and to determine the cohomology groups, one has to compute the homology of a chain complex. Kocherlakota [38] computed the differentials in the Morse complex for general R -spaces up to sign. As he remarks, the open cells determined by the Morse function coincide with the Bruhat cells, so his computations determine the incidence coefficients which are 0 or ± 2 .

In order to compute the integer or rational coefficient cohomology groups, the signs are also required. The latest development is the work of Rabelo and San Martin [46], who complete Kocherlakota’s computation for R -spaces by determining the signs of the incidence coefficients via a CW homology approach.

Our first aim is to compute the incidence coefficients of the Schubert cells in real flag manifolds via a slightly different approach, namely by using the geometry of the Schubert cells. We give an alternative proof of Kocherlakota’s theorem, then we compute the signs (Theorems 3.10, 3.13, 3.16). These results can be summarized as follows:

Theorem 3.10 *The incidence coefficient of the Schubert cells Ω_I and Ω_J is given by*

$$[\Omega_I, \Omega_J] = \begin{cases} 0, & N_I(a, b) \text{ even} \\ (-1)^{s(I,J)} 2, & N_I(a, b) \text{ odd} \end{cases}$$

where $N_I(a, b)$ and $s(I, J)$ are integers determined by the combinatorics of the ordered set partitions I and J , see (2.1), (3.5) and Theorem 3.16.

We expect that the method presented here also generalizes to R -spaces, however in this paper we only consider the real partial flag manifolds $Fl_{\mathcal{D}}^{\mathbb{R}}$. Our results are similar to [46], although the results are not directly comparable. Using Theorems 3.10 and 3.16, we computed several examples with SageMath’s homology package [52]. Based on

these computations, we formulated a conjecture stating that all torsion in $H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Z})$ has order exactly 2 (see also Theorem 6.1).

1.1.2 Cycles

Once the incidence coefficients are known, it is a nontrivial combinatorial problem to determine what the integer or rational cohomology groups are, which Schubert varieties are cycles and what the further generators are (i.e. which union of oriented Schubert cells). This is currently unsolved for general real flag manifolds $\text{Fl}_{\mathcal{D}}^{\mathbb{R}}$. The second contribution of this paper is that we determine which Schubert varieties are nonzero rational cycles in the case of even flag manifolds $\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}$, see Theorem 3.12. In particular, we obtain the following result (for the notation, see (2.1) and Section 3.7).

Theorem 3.12 *A basis of $H^*(\text{Fl}_{2\mathcal{D}}(\mathbb{R}^{2N}); \mathbb{Q})$ is given by*

$$H^*(\text{Fl}_{2\mathcal{D}}(\mathbb{R}^{2N}); \mathbb{Q}) = \left\langle [\sigma_{DI}] : I \in \binom{N}{\mathcal{D}} \right\rangle.$$

We also recover the result of Pontryagin on Schubert cycles in Grassmannians [44, Theorem 1], see Theorem 5.1. Using the incidence coefficients we also computed some small examples of geometric cycles generating $H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$ for general \mathcal{D} , see the tables of Appendix B. These tables illustrate the stark contrast of the general case with the simple descriptions of Theorems 3.12 and 5.1.

1.2 Structure constants

Once the cycles have been determined, the next step is to determine the multiplicative structure constants of the cycles. We will carry this out for $\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}$ by showing that they are circle spaces with rational coefficient cohomology [17,41], see Theorem 4.4, its Corollaries 4.5, 4.6. Namely, in Corollary 4.5 we obtain the following result.

Theorem (Corollary 4.5) *The structure constants of $[\sigma_{DI}^{\mathbb{R}}] \in H^*(\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$ agree with the structure constants of $[\sigma_I^{\mathbb{C}}] \in H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{C}}; \mathbb{Q})$:*

$$[\sigma_{DI}^{\mathbb{R}}] \cdot [\sigma_{DJ}^{\mathbb{R}}] = \sum_K c_{IJ}^K [\sigma_{DK}^{\mathbb{R}}] \iff [\sigma_I^{\mathbb{C}}] \cdot [\sigma_J^{\mathbb{C}}] = \sum_K c_{IJ}^K [\sigma_K^{\mathbb{C}}].$$

In the special case of Grassmannians, this follows from results of [23, III.3.2.3.E], and [20], see also Propositions 5.2, 5.3. In the context of algebraic geometry, the Chow-Witt rings of real Grassmannians have been recently considered in [57]; the similarity of Propositions 5.2, 5.3 with [57, Theorem 1.2] suggests that Corollaries 4.5, 4.6 have analogues for the Chow-Witt rings of even flag manifolds.

1.3 Characteristic classes

Returning to the complex case, another kind of description of the cohomology ring of the complex flag manifolds is given in terms of characteristic classes of their tautologi-

cal bundles. Namely, $H^*(\text{Fl}_{\mathcal{D}}(\mathbb{C}^N); \mathbb{Z})$ is generated as an algebra by the Chern classes $c_i(D_j)$ of the tautological quotient bundles $D_j = S_j/S_{j-1}$. In modern language, this can be formulated as surjectivity of the Kirwan map [35]. The relations are given by the identity $\prod_{j=1}^m c_*(D_j) = 1$, where c_* is the total Chern class, see e.g. [8, Chapter 23]. In the case of the Grassmannians, the relationship between these two descriptions is given by the *Giambelli formula*

$$[\sigma_\lambda] = \det(c_{\lambda_i+j-i}(Q)).$$

In the real case $G = \text{GL}(N, \mathbb{R})$, and a parabolic subgroup $P \leq G$, Pontryagin classes do not always generate the cohomology ring $H^*(G/P; \mathbb{Q})$; this is only the case if G and P have the same rank, i.e. even real flag manifolds $\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}$. In other words, the “rational real Kirwan map” is surjective iff $\text{rk } P = \text{rk } G$. In this case, we express $[\sigma_\lambda]$ in terms of Pontryagin classes, see Corollary 4.6.

Casian and Kodama [11] made a conjecture about the ring structure of $H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$ in the case of $\mathcal{D} = (k, n - k)$, i.e. Grassmannians $H^*(\text{Gr}_k(\mathbb{R}^n); \mathbb{Q})$, which has been proved even equivariantly via different approaches, see [10,30,47,50]. Recently, He [32] determined the cohomology ring $H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$ for arbitrary \mathcal{D} . We state He’s theorem in the form convenient for us in Theorem A.3.

1.4 Summary of the results on $H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$

The new results of this paper partially answer the following questions. Given a real partial flag manifold $\text{Fl}_{\mathcal{D}}^{\mathbb{R}}$:

- (Q1) Which Schubert varieties σ_I are cycles? ($I \in \binom{[N]}{\mathcal{D}}$, see (2.1)) Which ones are nonzero in $H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$? Which linear combinations of Schubert cells are the remaining generators?
- (Q2) What are the multiplicative structure constants of the cycles?
- (Q3) What are the relations between Pontryagin classes of the tautological bundles? What further additional generators r_i are there and what are the relations?
- (Q4) How to express one set of generators from the other? $\sigma_I(p_i, r_i) = ?$ $p_i(\sigma_I) = ?$, $r_i(\sigma_I) = ?$

Theorems 3.12, 5.1 and Appendix B are results of type (Q1). Theorem 4.4, Corollary 4.5, and Propositions 5.2, 5.3 concern (Q2). He’s Theorem A.3 [32] answers (Q3) in rational coefficient cohomology. Corollary 4.6 concerns (Q4).

Note, that (Q1), (Q3) and (Q4) imply (Q2) rationally, at least in theory; in practice giving combinatorial rules to compute the structure constants is not immediate and has been extensively studied in the complex case for different kind of cohomology theories by Littlewood-Richardson rules, checkers, puzzles [25,37,53]. By Corollary 4.5, the same combinatorial descriptions can be applied in the even real case $\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}$.

1.5 Integer coefficients

The final step is determining the integer coefficient cohomology. The formulas for the incidence coefficients (Theorems 3.10, 3.16) can be used in a computational homology program, to compute the cohomology groups and their generators. We calculated several examples using SageMath's homology package (all partial flag manifolds of \mathbb{R}^N , $N \leq 7$ and some up to \mathbb{R}^{11} , see Appendix B for some of the results). Based on these computations, we make the following conjecture:

Conjecture *Every torsion element in $H^*(\mathrm{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Z})$ is of order exactly two.*

If the conjecture is true, then the cohomology groups can be completely determined (cf. Proposition 6.2). The conjecture is known in the following cases. For infinite Grassmannians it is classical [6] that all torsion is of order 2. For finite Grassmannians, this is a result of Ehresmann [16]. We prove the following result:

Theorem 6.1 *Every torsion element in $H^*(\mathrm{Fl}_{2\mathcal{D}}^{\mathbb{R}}; \mathbb{Z})$ is of order exactly two.*

In particular, the integral classes of the Schubert cycles $[Z]$ are completely determined by their rational and mod 2 reductions. The proof of this theorem involves computing the Bockstein cohomology of $X := \mathrm{Fl}_{2\mathcal{D}}^{\mathbb{R}}$:

$$H_{\beta}^*(X) := (H^*(X; \mathbb{F}_2); \mathrm{Sq}^1),$$

($\mathrm{Sq}^1 \circ \mathrm{Sq}^1 = 0$); $H_{\beta}^*(X)$ is the first page of the Bockstein Spectral Sequence. In the computations, we use that $\mathrm{Sq}^1[\sigma_I]$ equals the sum of those Schubert classes $[\sigma_J]$ which have nonzero incidence coefficient with $[\sigma_I]$ (Proposition 6.3) this extends an observation of Lenart [40]. This concludes the determination of the cohomology groups $H^*(\mathrm{Fl}_{2\mathcal{D}}; \mathbb{Z})$. We do not take on the task of determining the integer coefficient ring structure.

1.6 Applications – real enumerative geometry

Using the Schubert cycle description of the rational cohomology ring structure, we give an application to real enumerative geometry. Whereas in the complex case, the answer to an enumerative geometry problem is a single number, in the real case, the answer is a list of possible numbers, depending on the generic configuration. In general, very little is known about the complete range of such numbers. In the case of flag manifolds, the enumerative geometric problems are called Schubert problems and in general, the range of possible solutions is unknown. However, the cohomology ring calculation provides a lower bound. In many cases, the lower bound is 0, however in some cases, there is a meaningful lower bound, see Proposition 7.1.

2 Preliminaries

In this section we recall the general definition of the Vassiliev complex and introduce some notation for the geometry of real flag manifolds.

2.1 Vassiliev complex - incidence coefficients

Throughout this section let $(X_\alpha)_{\alpha \in A}$ be a stratification of a smooth manifold X where each stratum is contractible. Vassiliev [55], [2, Ch. 4.2] gave a method for computing the cohomology of X and determining when the closure of a stratum has a fundamental cohomology class (or in another terminology is a ‘cycle’). Let $F_i := X \setminus \overline{X^{i+1}}$ be the open codimension filtration of X , where X^i is the union of the i -codimensional strata. The *Vassiliev complex* is the bottom row of the E_1 -page of the spectral sequence associated to this filtration with connecting homomorphism

$$d : H^p(F_p, F_p \setminus X^p) \rightarrow H^{p+1}(F_{p+1}, F_{p+1} \setminus X^{p+1}),$$

The cohomology of the Vassiliev complex computes $H^*(X; \mathbb{Z})$, since the spectral sequence of the filtration degenerates on the E_2 -page by the contractibility assumption on the strata. Furthermore, since the strata are contractible, their normal bundles are trivial; let us fix a coorientation on each stratum. The k -cochains in the Vassiliev complex are the linear combinations of the k -codimensional strata X_α with their fixed coorientation, and the differential d can be written as

$$dX_\alpha = \sum_{\text{codim } X_\beta = \text{codim } X_\alpha + 1} n_{\alpha\beta} X_\beta.$$

We will also use the notation $[X_\alpha, X_\beta]$ instead of $n_{\alpha\beta}$. In case one can find a submanifold D of X intersecting all strata of $\overline{X_\alpha}$ transversally, one can compute the incidence coefficients $n_{\alpha\beta}$ geometrically as follows ([2,55], see also [19]). If $X_\beta \not\subseteq \overline{X_\alpha}$ then $n_{\alpha\beta} = 0$.

Let $A := X_\alpha$ be a k -codimensional and $B := X_\beta \subseteq \overline{X_\alpha}$ be a $(k + 1)$ -codimensional stratum, with normal bundles ν_α, ν_β respectively (these are trivial by the contractibility assumption). Let $D := D^{k+1}$ be a $(k + 1)$ -dimensional submanifold of X that intersects all strata of \overline{A} transversally and intersects B in a point b . Let $L := D \cap A$ which by transversality is a disjoint union of connected curves L_i , whose closure contains b . For each L_i , choose a splitting s of the quotient map $q : TX|_{L_i} \rightarrow \nu_\alpha|_{L_i}$, such that

$$TD|_{L_i} = TL_i \oplus \nu_\alpha|_{L_i},$$

where $\nu_\alpha|_{L_i} \subseteq TX|_{L_i}$ via the splitting s . Then TL_i is oriented by taking the orientation pointing towards b and ν_α is oriented by the coorientation of A , so they determine an orientation of $TD|_{L_i}$ (fix the convention of taking TL_i first, then $\nu_\alpha|_{L_i}$). This extends to an orientation O_1 of TD at b . Since D is transversal to B , the orientation of $\nu_\beta|_b$ determines an orientation O_2 of $TD|_b$. If the two orientations O_1 and O_2 agree for L_i , then set $n^i_{\alpha\beta} := +1$, otherwise -1 . Then $n_{\alpha\beta} = \sum_i n^i_{\alpha\beta}$.

One can show that X_α is a cycle in the Vassiliev complex, iff $Z = \overline{X_\alpha}$ has a fundamental cohomology class: from now on we will simply say that Z is a cycle. We will compute the Vassiliev complex of real partial flag manifolds for the stratification by Schubert cells in Sect. 3.

2.2 Geometry of flag manifolds

This section is standard, see [9,25] for the complex case. We include it to fix some notation and properties that we will use in the computations of Sect. 3. We are interested in the real case, so $GL(N)$ denotes $GL(N, \mathbb{R})$ and B^+ is the subgroup of real upper triangular matrices.

2.2.1 Schubert varieties, orbit structure

Denote the standard basis in \mathbb{R}^N by e_1, \dots, e_N , their one-dimensional spans by $\varepsilon_i = \langle e_i \rangle$, and let E_\bullet be the standard flag, which consists of the subspaces $E_j = \bigoplus_{i=1}^j \varepsilon_i$. The stabilizer of E_\bullet in $G := GL(N)$ is B^+ . Choose a parabolic subgroup, i.e. $B^+ \subseteq P \subseteq G$. Similarly to the complex case,

$$P = GL(\mathcal{D}), \quad \text{for some } \mathcal{D} = (d_1, \dots, d_m), \sum d_i = N$$

which is the subgroup of block upper-triangular matrices with elements of $GL(d_i)$ on the diagonal blocks and arbitrary entries above the blocks.

The corresponding homogeneous space $X = G/P$ is the partial flag manifold $Fl_{\mathcal{D}}(\mathbb{R}^N)$. Using this notation, d_i denotes the difference in the dimensions of the flags. Let their dimensions be $\mathcal{S} = (s_1, \dots, s_m)$, where $s_1 = d_1$, and $s_i - s_{i-1} = d_i$ for $i > 1$.

The B^+ -orbits on X are called *Bruhat cells* $\Omega_I(E_\bullet)$. Each of these contains a unique coordinate flag $E_\bullet^I \in Fl_{\mathcal{D}}(\mathbb{R}^N)$ (2.2) by the Bruhat decomposition [9, Section 1.2] or [15, Corollary 3.8] for the real case. These in turn are indexed by *ordered set partitions* $I \in OSP(\mathcal{D})$, where

$$OSP(\mathcal{D}) := \binom{N}{\mathcal{D}} = S_N / (S_{d_1} \times \dots \times S_{d_m}). \tag{2.1}$$

By definition, an element of $OSP(\mathcal{D})$ is a partition of the numbers $[N] := \{1, \dots, N\}$ to m parts of sizes d_1, \dots, d_m . In particular, the j th part is a subset of $[N]$ of size d_j , that we will denote by $I_j \in \binom{N}{d_j}$. In general, we will denote the set of k -element subsets of N by $\binom{N}{k}$. Using this indexing, for $I \in OSP(\mathcal{D})$, we denote by E_\bullet^I the coordinate flag $(E_1^I \subseteq E_2^I \subseteq \dots \subseteq E_m^I)$ whose r th term is

$$E_r^I = \bigoplus_{\substack{j \leq r \\ l \in I_j}} \varepsilon_l. \tag{2.2}$$

Notation. We will represent $I \in OSP(\mathcal{D})$ by the minimal length element in S_N in the coset of I : list elements of I_1 in increasing order, then elements of I_2 in increasing order etc. – the I_j separated by brackets or commas. In particular, for complete flag manifolds $\mathcal{D} = (1^N)$ this coincides with the one-line notation of $OSP(\mathcal{D}) = S_N$,

the same convention as [25], see also [26, p. 20]. It is sometimes convenient to write $I \in \binom{N}{\mathcal{D}}$ as a function: $I : [N] \rightarrow [m]$ satisfying $|I^{-1}(j)| = d_j$ for all j .

Given a general complete flag A_\bullet , the Bruhat cells coincide with the following *Schubert cell* description:

$$\Omega_I(A_\bullet) = \{F_\bullet \in \text{Fl}_{\mathcal{D}}(\mathbb{R}^N) : \dim F_i \cap A_k = r_I(i, k)\}, \tag{2.3}$$

where $r_I(i, k) = |\{l \in I_1 \cup \dots \cup I_i : l \leq k\}|$. When we omit the flag from the notation Ω_I , that means that we take the standard flag E_\bullet . For the dimension of Ω_I , $I \in \text{OSP}(\mathcal{D})$, introduce $\ell(I)$ to be the number of *inversions* (i.e. pairs of elements in reverse order):

$$\ell(I) := |\{(a, b) : a > b, a \in I_\alpha, b \in I_\beta, \alpha < \beta\}|. \tag{2.4}$$

Then $\dim \Omega_I = \ell(I)$ (see Proposition 2.3).

The closure of the orbit Ω_I is called a *Schubert variety* and is denoted σ_I . If a Schubert variety σ_I is a cycle (in the sense discussed in Sect. 2.1), we call it a *Schubert cycle* and its class $[\sigma_I]$ a *Schubert class*. The orbit structure is described by the *Bruhat order* (cf. [38, Theorem 2.3.2] for the real case):

$$\sigma_I = \bigcup_{J \leq I} \Omega_J \tag{2.5}$$

where $J \leq I$ iff $(J_1 \cup \dots \cup J_i)_{rtiv} \leq (I_1 \cup \dots \cup I_i)_{rtiv}$ for all i , where *rtiv* means “reordered to increasing value” and the partial order $(a_1, \dots, a_j) \leq (b_1, \dots, b_j)$ is the lexicographic one. This is also equivalent to $r_I(i, k) \geq r_J(i, k)$ for all i, k .

2.2.2 Tangent bundle of $\text{Fl}_{\mathcal{D}}(\mathbb{R}^N)$

We recall a well-known decomposition of the tangent bundle of X in terms of tautological bundles.

Let $G := \text{GL}(N)$ and $P \subseteq G$ be a parabolic subgroup; $P = \text{GL}(\mathcal{D})$. P has projections to subgroups $p_i : P \rightarrow \text{GL}(s_i)$ which are homomorphisms, whose defining representations induce the tautological bundles. For example, the defining representation of $\text{GL}(s_i)$ on \mathbb{R}^{s_i} induces the i th tautological bundle over G/P :

$$S_i \cong \text{GL}(N) \times_P \mathbb{R}^{s_i}.$$

The quotient and difference bundles are defined by the following exact sequences of bundles over X :

$$\begin{aligned} 0 \longrightarrow S_i \longrightarrow \mathbb{R}^N \longrightarrow Q_i \longrightarrow 0 \\ 0 \longrightarrow S_{i-1} \longrightarrow S_i \longrightarrow D_i \longrightarrow 0 \end{aligned} \tag{2.6}$$

with the convention $S_0 = 0$. Notice that $s_i = \dim S_i$, $d_i = \dim D_i$, and let $q_i = \dim Q_i$. Recall the following general fact about the tangent bundle of homogeneous spaces:

Proposition 2.1 [27, Lemma II.2.3.1. (p. 132)] *Let $X = G/H$ be a homogeneous space and let \mathfrak{g} and \mathfrak{h} denote the Lie algebras of G and H respectively. Then the G -equivariant vector bundle $TX \rightarrow X$ fits into the short exact sequence of G -equivariant bundles*

$$0 \rightarrow G \times_H \mathfrak{h} \rightarrow G \times_H \mathfrak{g} \rightarrow G \times_H (\mathfrak{g}/\mathfrak{h}) \cong TX \rightarrow 0$$

where H acts on \mathfrak{g} , \mathfrak{h} via the adjoint representation.

Corollary 2.2

$$TX \cong \bigoplus_{i=1}^{m-1} \text{Hom}(D_i, Q_i) \cong \bigoplus_{1 \leq i < j \leq m} \text{Hom}(D_i, D_j)$$

Proof Apply the Proposition to the homogeneous space $\text{Fl}_{\mathcal{D}}(\mathbb{R}^N) = \text{GL}(N)/\text{GL}(\mathcal{D})$. □

A choice of the basis $e_i \in \mathbb{R}^N$ induces splittings $Q_i \rightarrow \mathbb{R}^N$, $D_i \rightarrow \mathbb{R}^N$, which is not essential, but facilitates computations, in particular it realizes TX as a subbundle of $\text{End}(\mathbb{R}^N)$. To alleviate notation, from now on, we will use an abuse of notation and write $N_I \Omega_I$ instead of $N_{E^I} \Omega_I$, where E^I_\bullet is the coordinate flag corresponding to the ordered set partition I introduced in (2.2). Then the tangent and normal spaces of Ω_I can be identified as follows:

Proposition 2.3 *The tangent and normal spaces of Ω_I at E^I_\bullet , $I \in \text{OSP}(\mathcal{D})$ are given by*

$$T_I \Omega_I = \bigoplus_{(c,d) \in T_I} \varepsilon_{cd}, \quad N_I \Omega_I = \bigoplus_{(c,d) \in N_I} \varepsilon_{cd}$$

where $\varepsilon_{cd} = \text{Hom}(\varepsilon_c, \varepsilon_d)$ and

$$T_I := \{(c, d) \in [N]^2 : c > d, I(c) < I(d)\}, \quad N_I := \{(c, d) \in [N]^2 : c < d, I(c) < I(d)\}.$$

In particular, the dimension of Ω_I is given by $|T_I| = \ell(I)$.

Using the identification $TX \subseteq \text{End}(\mathbb{R}^N)$ as a subbundle and Corollary 2.2, the proof consists of computing the stabilizer subgroups $\text{Stab}_{B^+}(E^I_\bullet)$, we omit the details.

2.2.3 Direct sum maps

We are going to make use of the following natural maps between flag manifolds. Let $\mathcal{D}_1 = (d^1_i) \in \mathbb{N}^m$, $\mathcal{D}_2 = (d^2_i) \in \mathbb{N}^m$ be two ordered sets of natural numbers, where

we allow zero and let $\mathcal{D}_1 + \mathcal{D}_2 = (d_i^1 + d_i^2)$ be their element-wise sum. Let A_1 be a vector space of dimension $\sum d_i^1$, and let A_2 be a vector space of dimension $\sum d_i^2$. The direct sum of A_1 and A_2 induces the following *direct sum map* of flag manifolds:

$$F_{\mathcal{D}_1, \mathcal{D}_2} : \text{Fl}_{\mathcal{D}_1}(A_1) \times \text{Fl}_{\mathcal{D}_2}(A_2) \hookrightarrow \text{Fl}_{\mathcal{D}_1 + \mathcal{D}_2}(A_1 \oplus A_2)$$

defined by

$$F_{\mathcal{D}_1, \mathcal{D}_2} \left(F_{\bullet}^1, F_{\bullet}^2 \right)_{\kappa} := F_{\kappa}^1 \oplus F_{\kappa}^2.$$

A direct sum decomposition $V = \bigoplus_i A_i$ induces a direct sum decomposition

$$\text{End}(V) = \bigoplus_{i,j} \text{Hom}(A_i, A_j),$$

in particular we obtain inclusions $\iota_j : \text{End}(A_j) \hookrightarrow \text{End}(V)$.

Proposition 2.4 *Let $\text{Fl}_{\mathcal{D}_i}(A_i)$, $i = 1, 2$ be two flag manifolds with $\mathcal{D}_i \in \mathbb{N}^m$, and let $E_{\bullet}^2 \in \text{Fl}_{\mathcal{D}_2}(A_2)$ be a fixed flag. Then*

$$f : \text{Fl}_{\mathcal{D}_1}(A_1) \rightarrow \text{Fl}_{\mathcal{D}_1 + \mathcal{D}_2}(A_1 \oplus A_2)$$

defined by $f := F_{\mathcal{D}_1, \mathcal{D}_2}(\cdot, E_{\bullet}^2)$ is an isomorphism onto its image, and

$$df : T \text{Fl}_{\mathcal{D}_1} \rightarrow T \text{Fl}_{\mathcal{D}_1 + \mathcal{D}_2}$$

coincides with $\iota_1|_{T \text{Fl}_{\mathcal{D}_1}}$, where $T \text{Fl}_{\mathcal{D}_1} \subseteq \text{End}(A_1)$ and $T \text{Fl}_{\mathcal{D}_1 + \mathcal{D}_2} \subseteq \text{End}(A_1 \oplus A_2)$ are subbundles using the identification determined by the bases $(a_i^1 \in A_1)$, $(a_i^2 \in A_2)$.

Proof (Sketch of proof) The direct sum map is a $\text{GL}(A_1) \times \text{GL}(A_2) \subseteq \text{GL}(A_1 \oplus A_2)$ -equivariant embedding, which implies the first statement. Denote the tautological difference bundles over $\text{Fl}_{\mathcal{D}_i}(A_i)$ by D_i^j , $i = 1, \dots, m$, $j = 1, 2$ and over $\text{Fl}_{\mathcal{D}_1 + \mathcal{D}_2}(A_1 \oplus A_2)$ denote them by D_i , $i = 1, \dots, m$. Using the splittings $D_i^j \hookrightarrow A_j$ and $D_i \hookrightarrow A_1 \oplus A_2$ for $i = 1, \dots, m$, $j = 1, 2$:

$$D_i|_{\text{Fl}_{\mathcal{D}_1} \times \text{Fl}_{\mathcal{D}_2}} = D_i^1 \oplus D_i^2.$$

The second part of the claim then follows from commutativity of the following diagram of bundles over $\text{Fl}_{\mathcal{D}_1}$:

$$\begin{CD} \bigoplus_{i < j} \text{Hom}(D_i^1, D_j^1) @>>> \bigoplus_{i < j} \text{Hom}(D_i^1 \oplus D_i^2, D_j^1 \oplus D_j^2) \\ @VVV @VVV \\ \text{End}(\bigoplus_{i=1}^m D_i^1) @>\iota_1>> \text{End}(\bigoplus_{i=1}^m D_i^1 \oplus D_i^2) \end{CD}$$

□

3 The Vassiliev complex of $\mathrm{Fl}_{\mathcal{D}}^{\mathbb{R}}$

In this section we compute the Vassiliev complex of $\mathrm{Fl}_{\mathcal{D}}^{\mathbb{R}}$ as described in Sect. 2.1, whose cohomology computes $H^*(\mathrm{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Z})$. The stratification is given by the Schubert cells Ω_I . Explicitly, we determine the incidence coefficients $[\Omega_I, \Omega_J]$. To compute the coefficients $[\Omega_I, \Omega_J]$, one has to coorient each Ω_I , and compare these coorientations by extending them to the adjacent orbits Ω_J along transversal submanifolds D as described in Sect. 2.1. The computations have many similarities to the one given by Kocherlakota, but instead of Morse theory we emphasize the geometry of the Schubert cells. Let us give a brief outline of the proof.

In Sect. 3.1 we define the coorientation of the Schubert cells Ω_I . In Sect. 3.2 we define the transversal submanifolds D to be the opposite Bruhat cells. The intersection of $W := \Omega_I \cup \Omega_J$ with D is a *Richardson curve* $R \cong \mathbb{R}P^1$. In Sect. 3.3 we show that $[\Omega_I, \Omega_J]$ is 0 or ± 2 depending on whether the restriction of the normal bundle $\nu(W)|_R$ is trivial or not. To determine triviality of $\nu(W)|_R$ we decompose it into a direct sum of line bundles, which is obtained in Sects. 3.4–3.6. This yields a combinatorial description of $[\Omega_I, \Omega_J]$ in terms of the number of Möbius bundles over R . In Sect. 3.7 using this combinatorial description, we determine which Schubert varieties σ_I are nonzero rational cycles in the even case $\mathrm{Fl}_{2\mathcal{D}}^{\mathbb{R}}$. In Sect. 3.8 we relate our computations to the theorem of Kocherlakota. By considering local orientations of $\nu(W)|_R$, we determine the sign of $[\Omega_I, \Omega_J]$ in Sect. 3.9. To conclude the chapter we illustrate the results on $\mathrm{Fl}(\mathbb{R}^4)$. We will use the notation of Sect. 2.2.

We remark that in the case of real (and complex) flag manifolds, each B^+ -orbit is homeomorphic to an affine space, so the orbit stratification yields a cell decomposition. Therefore computing the incidence coefficients agrees with the incidence coefficients of the CW complex, which have been examined by Ehresmann [16] for Grassmannians, later by Kocherlakota for generalized real flag manifolds (R -spaces) using the Morse complex [38] and most recently by Rabelo and San Martin [46] using CW homology (for the general case of R -spaces).

3.1 Coorientation of the strata

We describe the Vassiliev complex of $X = \mathrm{Fl}_{\mathcal{D}}(\mathbb{R}^N)$, $\mathcal{D} = (d_1, \dots, d_m)$. First, we coorient all cells by fixing a coorientation of Ω_I at E_{\bullet}^I (see Sect. 2.2 for the notation). Using the decomposition of the tangent and normal spaces given in Proposition 2.3, orient both the tangent and normal spaces by the lexicographic ordering of those $e_{kl} = (e_k \mapsto e_l)$ which appear in them. Since Ω_I is contractible, the orientation of the normal space $N_I \Omega_I$ at E_{\bullet}^I determines a coorientation on the whole of Ω_I . In fact, we will not make use of the choice of orientations up until Sect. 3.9 when we determine signs of the incidence coefficients.

3.2 Richardson curves

Our aim is to determine the incidence numbers $[\Omega_I, \Omega_J]$, for $\ell(J) = \ell(I) - 1$ and $J \leq I$ (recall the notations (2.4) and (2.5)). The Bruhat order implies that J is obtained

from I by interchanging $a \in I_\alpha$ with some $b \in I_\beta, a > b, \alpha < \beta$ (this follows e.g. from [38, Theorem 2.3.2]). We call such I, J (and Ω_I, Ω_J) *adjacent* and fix this data in the upcoming discussion.

According to the construction of the Vassiliev complex (Sect. 2.1), we will fix a transversal submanifold to Ω_J at E_\bullet^J ; natural candidates are the dual Schubert cells, i.e. the orbits of the opposite Borel subgroup B^- . The B^- -orbits $B^-E_\bullet^J$ have the following characterization:

$$B^-E_\bullet^J = \Omega_{J^D}(E_\bullet^\vee) = \left\{ F_\bullet \in \text{Fl}_{\mathcal{D}}(\mathbb{R}^N) : \dim F_i \cap E_k^\vee = r_{J^D}(i, k) \right\}$$

where $J^D = (J_1^D, J_2^D, \dots, J_m^D), J_i^D := N + 1 - J_i$ and E_\bullet^\vee is the standard dual flag, whose i th subspace is

$$E_i^\vee = \langle e_N, \dots, e_{N-i+1} \rangle.$$

Since the flags $E_\bullet, E_\bullet^\vee$ are transverse, all B^- -orbits are transverse to Ω_I , so $B^-E_\bullet^J$ is a transversal submanifold to Ω_J at E_\bullet^J . For general I, J , the intersections $\sigma_I^J = \sigma_I(E_\bullet) \cap \sigma_{J^D}(E_\bullet^\vee)$ are called *Richardson varieties*. To determine the incidence numbers $[\Omega_I, \Omega_J]$, we will be interested in the *Richardson curves* σ_I^J when $\ell(J) = \ell(I) - 1$ and $J \leq I$. Intuitively, the Richardson curve is the curve between the coordinate flags E_\bullet^I and E_\bullet^J obtained by continuously exchanging the coordinates ε_a and ε_b in E_\bullet^I .

More precisely, in terms of the direct sum maps of Proposition 2.4, the Richardson curve σ_I^J is the isomorphic image of $f : \mathbb{P}(A_1) \hookrightarrow \text{Fl}_{\mathcal{D}}(\mathbb{R}^N)$ for $A_1 := \varepsilon_a \oplus \varepsilon_b, A_2 := A_1^\vee = \bigoplus_{i \neq a, b} \varepsilon_i$ and $E_\bullet := E_\bullet^I \cap E_\bullet^J$,

$$f(\cdot) = F_{\mathcal{D}_1, \mathcal{D}_2}(\cdot, E_\bullet), \quad \mathcal{D}_2 = (d_1, \dots, d_\alpha - 1, \dots, d_\beta - 1, \dots, d_m),$$

for $\mathcal{D} = \mathcal{D}_1 + \mathcal{D}_2$ and $\mathcal{D}_1 = (1, 1)$ in positions α, β . Note that σ_I^J is isomorphic to $\mathbb{R}P^1$. The isomorphism f induces tautological bundles $\rho \rightarrow \sigma_I^J$ on the Richardson curves as follows. Let

$$\tilde{f} = (\text{id}, f) : A_1 \times \mathbb{P}(A_1) \rightarrow A_1 \times \text{Fl}_{\mathcal{D}}$$

be the trivial bundle map covering f and let $\tau \rightarrow \mathbb{P}(A_1)$ denote the tautological subbundle of A_1 . Then we can define a tautological bundle over σ_I^J by

$$\rho := \tilde{f}(\tau) \tag{3.1}$$

which is a subbundle of the trivial bundle $A_1 \subseteq \mathbb{R}^N$ over σ_I^J .

Note that the intersection $\Omega_I \cap B^-E_\bullet^J$ is the Richardson curve minus two points $\sigma_I^J \setminus \{E_\bullet^I, E_\bullet^J\}$, i.e. $\mathbb{R}P^1$ minus two points. We remark that the connected components of this intersection correspond to the *pairs of flows* in the terminology of Kocherlakota [38].

Fig. 1 An illustration of Richardson curves

3.3 Incidence coefficients

Let $W := \Omega_I \cup \Omega_J$ and let $D := B^- E^J \cup B^- E^I$ which is a transversal submanifold to Ω_J at E^J . Note that W and D are smooth. Indeed, complex Schubert varieties $\sigma_I^C \subseteq \text{Fl}_D^C$ are normal [9], so their singularities are of codimension at least 2 and are unions of Schubert cells. Therefore Ω_I^C union the adjacent complex Schubert cells is smooth. This also implies that W and D are smooth in the real case: by Whitney’s Lemma [58, Lemma 9] $\text{Reg}(\sigma_I^R) = \text{Reg}(\sigma_I^C)(\mathbb{R})$, i.e. the regular points of σ_I^R are the real points of the regular points of σ_I^C . For an illustration of the notation, see Fig. 1.

The Richardson curve $R := \sigma_I^J$ is the transversal intersection of W and D (the intersection of the two surfaces on Fig. 1). Let $R_+ \cup R_- = R \setminus \{I, J\}$ denote the two branches of the Richardson curve (the choice of the sign is arbitrary). Note that R_\pm are the curves denoted by L_i in Sect. 2.1. To compute $[\Omega_I, \Omega_J]$, we are going to use smoothness of W and D .

Proposition 3.1 *With the previous notations, the incidence coefficients are determined up to sign by the triviality of the normal bundle $\nu(W \hookrightarrow X)|_R$:*

$$[\Omega_I, \Omega_J] = \begin{cases} 0 & \text{if } \nu(W \hookrightarrow X)|_R \text{ is trivial} \\ \pm 2 & \text{if } \nu(W \hookrightarrow X)|_R \text{ is nontrivial} \end{cases}$$

Triviality of $\nu(W \hookrightarrow X)|_R$ is determined by the first Stiefel-Whitney class $w_1(\nu(W \hookrightarrow X)|_R)$.

Proof Since R is the transversal intersection of W and D , there is a short exact sequence

$$0 \longrightarrow TR \longrightarrow TD|_R \longrightarrow \nu(W)|_R \longrightarrow 0$$

where $\nu(W)$ is the normal bundle of W in X . Take a splitting of this short exact sequence:

$$TD|_R = TR \oplus N_W.$$

For the differentials of the Vassiliev complex, one has to compare the following two orientations for each branch R_{\pm} :

- $TD|_J$ oriented by the coorientation of Ω_J
- $N_W|_J$ oriented by extending the coorientation of $\Omega_I|_{R_{\pm}}$ to J and TR oriented towards J on both branches R_{\pm} .

To compute $[\Omega_I, \Omega_J]$ up to sign, it is enough to compare how the two coorientations $\Omega_I|_{R_{\pm}}$ extend to $N_W|_J$. This amounts to deciding orientability of the bundle $N_W \cong \nu(W)|_R$. If N_W is orientable, then since its orientation on both branches agrees with its orientation at I , the orientations of $N_W|_{R_{\pm}}$ extend to J identically. Since the orientations of TR induced by the orientations of TR_{\pm} differ at J , in this case $[\Omega_I, \Omega_J] = 0$.

If N_W is not orientable, then since the orientations of $N_W|_{\bar{R}_+}$ and $N_W|_{\bar{R}_-}$ agree at I , they are different at J . In this case $[\Omega_I, \Omega_J] = \pm 2$. Finally, vector bundles over S^1 are classified by their first Stiefel-Whitney class w_1 . □

In the upcoming Sects. 3.4–3.6 we determine triviality of $\nu(W)|_R$ by giving linearly independent line subbundles $\lambda_{cd} \subseteq \nu(W)|_R$ spanning it (Theorem 3.5), and counting the nontrivial ones (since $R \cong S^1$, each λ_{cd} is either a Möbius bundle or a trivial one). Kocherlakota computes the incidence coefficients (up to sign) using a very similar idea: he computes the relative orientations of pairs of flows from I to J , which are in our terminology the branches of the Richardson curves.

Remark 3.2 As we have mentioned before, since Schubert varieties are normal, the singularities have codimension at least 2 and the singular part is a union of Schubert cells. Therefore Ω_I union the adjacent cells is smooth. Let us denote this union by $\overset{\circ}{\sigma}_I$. This gives a new stratification of σ_I , with no one-codimensional stratum, but now the strata are no longer contractible. Now σ_I is a cycle if and only if $\overset{\circ}{\sigma}_I$ is coorientable. Indeed, by the previous Proposition, this is the information encoded in $[\Omega_I, \Omega_J]$: the normal bundle of $\overset{\circ}{\sigma}_I$ restricted to the Richardson curve σ_I^J is orientable iff this coefficient vanishes. Then $\overset{\circ}{\sigma}_I$ is coorientable iff $\nu(\overset{\circ}{\sigma}_I)$ restricted to the Richardson curve σ_I^J is orientable (trivial) for all adjacent J .

For general stratified submanifolds, the union with the one-codimensional strata is not smooth, but when it is, this method is sufficient to decide cycleness. However to compute the cohomology groups we need more, namely to determine the incidence coefficients, which cannot be deduced only from orientability.

3.4 Splitting $TX|_R$

To determine triviality of $\nu(W)|_R$, we split $TX|_R$ into line subbundles λ_{cd} , parametrized by $T_I \sqcup N_I$ (for the notation T_I, N_I , see Proposition 2.3). We will show that $TW|_R = \bigoplus_{(c,d) \in T_I} \lambda_{cd}$, so $\bigoplus_{(c,d) \in N_I} \lambda_{cd}$ is isomorphic to $\nu(W)|_R$, see Theorem 3.5.

In (3.3) we will specify $\lambda_{cd} \rightarrow R$ as subbundles of $TX|_R \subseteq \text{End}(\mathbb{R}^N)$. In particular each λ_{cd} is of the form $\text{Hom}(\mu_1, \mu_2)$:

$$\mu_i \in \{\rho, \rho^\vee, \varepsilon_k : k \in [N]\},$$

where $\rho \rightarrow R$ is the tautological bundle defined in (3.1), and ρ^\vee denotes its orthogonal complement.

Recall the quotient bundles introduced in (2.6). A choice of a basis $e_i \in \varepsilon_i$ induces a scalar product on \mathbb{R}^N ; this realizes the quotient bundles Q_i, D_i as subbundles of \mathbb{R}^N . This induces the following splittings over $X = \text{Fl}_{\mathcal{D}}(\mathbb{R}^N)$:

$$\mathbb{R}^N = S_i \oplus Q_i = \bigoplus_{j=1}^m D_j = \bigoplus_{k=1}^N \varepsilon_k, \quad S_i = \bigoplus_{j=1}^i D_j, \quad Q_i = \bigoplus_{j=i+1}^m D_j$$

for all $i = 1, \dots, m$. By restricting to the Richardson curve $R = \sigma_I^J$,

$$D_i|_R = \begin{cases} \bigoplus_{j \in I_i} \varepsilon_j, & i \neq \alpha, \beta, \\ \rho \oplus \bigoplus_{a \neq j \in I_\alpha} \varepsilon_j, & i = \alpha \\ \rho^\vee \oplus \bigoplus_{b \neq j \in I_\beta} \varepsilon_j, & i = \beta \end{cases} \tag{3.2}$$

where $\rho \rightarrow R$ is the tautological bundle defined previously in (3.1). Then via the isomorphism

$$TX \cong \bigoplus_{i < j} \text{Hom}(D_i, D_j) \subseteq \text{End}(\mathbb{R}^N)$$

the decomposition (3.2) induces a splitting of $TX|_R$ into line bundles $\lambda_{cd} \rightarrow R$ parametrized by $(c, d) \in T_I \sqcup N_I$, defined as follows

$$\lambda_{cd} := \begin{cases} \text{Hom}(\rho, \rho^\vee), & \text{if } c = a, d = b \\ \text{Hom}(\rho, \varepsilon_d), & \text{if } c = a, I(a) < I(d) \leq I(b), d \neq b \\ \text{Hom}(\varepsilon_c, \rho^\vee), & \text{if } d = b, I(a) \leq I(c) < I(b), c \neq a \\ \varepsilon_{cd}, & \text{else.} \end{cases} \tag{3.3}$$

where in the else line we use that $\text{Hom}(\rho \oplus \rho^\vee, \varepsilon_k) = \text{Hom}(\varepsilon_a \oplus \varepsilon_b, \varepsilon_k)$.

3.5 The case of $\text{Fl}(\mathbb{R}^3)$

Next, we will show that $\{\lambda_{cd} : (c, d) \in T_I\}$ span $TW|_R$. We show this by reducing the general case $\text{Fl}_{\mathcal{D}}$ to the flag manifolds $\text{Fl}_{\mathcal{D}'}(\mathbb{R}^3)$. In this section we treat this special case: we compute the tangent bundles $TW'|_R$ for all Schubert varieties in $\text{Fl}_{\mathcal{D}'}(\mathbb{R}^3)$. Then the general case of $\text{Fl}_{\mathcal{D}}$ can be reduced to these results, by using direct sum maps $f : \text{Fl}_{\mathcal{D}'}(\mathbb{R}^3) \hookrightarrow \text{Fl}_{\mathcal{D}}$. This will be used in Sect. 3.6, where we show $\lambda_{cd} \subseteq TW'|_R$

Table 1 The bundle $T\sigma_I|_R/TR$, for $R = R_{ab} = \sigma_I^J$

(a, b)	(2,1)	(3,1)	(3,2)
σ_{321}	$\varepsilon_{32} \oplus \varepsilon_{31}$	$\varepsilon_{32} \oplus \varepsilon_{21}$	$\varepsilon_{31} \oplus \varepsilon_{21}$
σ_{231}	$\text{Hom}(\varepsilon_3, \rho^\vee)$	ε_{21}	–
σ_{312}	–	ε_{32}	$\text{Hom}(\rho, \varepsilon_1)$

by showing that $\lambda_{cd} \subseteq df(TW')$ for some smooth submanifold $W' \subseteq \text{Fl}_{\mathcal{D}'}(\mathbb{R}^3)$ with $f(W') \subseteq W$.

Let $\mathcal{D}' = (1, 1, 1)$, $\varepsilon_i = \langle e_i \rangle$ and E_\bullet be the standard flag, $E_i = \bigoplus_{j=1}^i \varepsilon_j$. Then

- $\sigma_{321} = X$
- $\sigma_{231} = \{F_\bullet : F_1 \subseteq E_2\}$
- $\sigma_{312} = \{F_\bullet : E_1 \subseteq F_2\}$
- $\sigma_{213} = \{F_\bullet : F_2 = E_2\}$
- $\sigma_{132} = \{F_\bullet : F_1 = E_1\}$
- $\sigma_{123} = \{F_\bullet : F_1 = E_1, F_2 = E_2\}$

where we use the one-line notation as discussed after (2.1). All of these Schubert varieties are smooth. The tangent bundles of the ≥ 2 -dimensional Schubert varieties are therefore:

$$\begin{aligned} T\sigma_{231} &= \text{Hom}(S_1, E_2/S_1) \oplus \text{Hom}(D_2, D_3), \\ T\sigma_{312} &= \text{Hom}(S_1, D_2) \oplus \text{Hom}(S_2/E_1, D_3), \\ T\sigma_{321} &= TX. \end{aligned} \tag{3.4}$$

Let $I, J \in \text{OSP}(\mathcal{D})$, $\ell(J) = \ell(I) - 1$ and J be obtained by interchanging $a \in I_\alpha$ with some $b \in I_\beta$, $a > b$, $\alpha < \beta$. If I is fixed, denote the Richardson curve σ_I^J by R_{ab} . Then by restricting to the Richardson curves $R = R_{ab}$, we obtain the expressions for $T\sigma_I|_R/TR$ described in Table 1, where $\varepsilon_{ij} = \text{Hom}_{\mathbb{R}}(\varepsilon_i, \varepsilon_j) \subseteq TX|_R$ and $\rho \rightarrow R$ is the tautological bundle as described earlier.

Table 1 shows that $\{\lambda_{cd} : (c, d) \in T_I\}$ defined in (3.3) spans $TW|_R$.

Similarly, for $\mathcal{D}' = (1, 2)$, $\text{Fl}_{\mathcal{D}'}(\mathbb{R}^3) = \mathbb{P}^2$, the only ≥ 2 -dimensional orbit is $I = (3)(1, 2)$, $J = (2)(1, 3)$ and

$$T\sigma_I|_R/TR = \text{Hom}(\rho, \varepsilon_1)$$

In case $\mathcal{D}' = (2, 1)$, $\text{Fl}_{\mathcal{D}'}(\mathbb{R}^3) = \text{Gr}_2(\mathbb{R}^3)$, the only ≥ 2 -dimensional orbit is $I = (2, 3)(1)$, $J = (1, 3)(2)$ and

$$T\sigma_I|_R/TR = \text{Hom}(\varepsilon_3, \rho^\vee)$$

3.6 Decomposing TW

Let us return to the general case $X = \text{Fl}_{\mathcal{D}}^{\mathbb{R}}$, and fix adjacent I, J , $a \in I_\alpha$, $b \in I_\beta$, $R = \sigma_I^J$, $W = \Omega_I \cup \Omega_J$ as before.

In this section we show that

$$TW|_R = \bigoplus_{(c,d) \in T_I} \lambda_{cd}$$

for λ_{cd} defined in (3.3). We show this by embedding smooth submanifolds $f : W' \hookrightarrow W$, such that $\lambda_{cd} \subseteq df(TW')|_R \subseteq TW|_R$ for all $(c, d) \in T_I$. The W' are submanifolds of smaller flag manifolds $\text{Fl}_{\mathcal{D}_1}$ which are embedded in $\text{Fl}_{\mathcal{D}}(\mathbb{R}^N)$ via the direct sum maps of Sect. 2.2.3.

For each $(c, d) \in T_I$ distinct from (a, b) we specify a direct sum map. Set $\vartheta := \{a, b, c, d\}$ which has 3 or 4 elements, and let

$$(\mathcal{D}_1)_\kappa := |\{k \in \vartheta : I(k) = \kappa\}|, \quad \kappa = 1, \dots, m$$

the number of distinct elements in ϑ which are in I_κ (this is either 0, 1 or 2). Let $\mathcal{D}_2 := \mathcal{D} - \mathcal{D}_1$ and $\Theta = \langle \varepsilon_k : k \in \vartheta \rangle$. The decomposition $\mathbb{R}^N = \Theta \oplus \Theta^\vee$ induces the direct sum map

$$F : \text{Fl}_{\mathcal{D}_1}(\Theta) \times \text{Fl}_{\mathcal{D}_2}(\Theta^\vee) \rightarrow \text{Fl}_{\mathcal{D}}(\mathbb{R}^N).$$

Let $E_\bullet^{I'J'} := E_\bullet^{I'} \cap E_\bullet^{J'} \in \text{Fl}_{\mathcal{D}_2}(\Theta^\vee)$. Define the embedding $f : \text{Fl}_{\mathcal{D}_1}(\Theta) \hookrightarrow \text{Fl}_{\mathcal{D}}(\mathbb{R}^N)$ by $F(\cdot, E_\bullet^{I'J'})$.

Proposition 3.3 *Given adjacent $I, J \in \text{OSP}(\mathcal{D})$, there exist (unique) $I', J' \in \binom{[\mathcal{D}]_1}{1}$, such that the following diagram commutes:*

$$\begin{CD} R'^C @>>> W'^C @>>> \text{Fl}_{\mathcal{D}_1}(\Theta) \\ @V \cong VV @VV \downarrow V @VV f V \\ R^C @>>> W^C @>>> \text{Fl}_{\mathcal{D}}(\mathbb{R}^N) \end{CD}$$

where $R' = \sigma_{I'}^{J'} \subseteq \text{Fl}_{\mathcal{D}_1}(\Theta)$, $W' = \Omega_{I'} \cup \Omega_{J'} \subseteq \text{Fl}_{\mathcal{D}_1}(\Theta)$ are smooth submanifolds.

Proof Since f is an embedding, $E_\bullet^{I'}$ and $E_\bullet^{J'}$ have at most one preimage each. There are unique order preserving maps

$$n : \{1, \dots, |\vartheta|\} \rightarrow \vartheta, \quad p : \{1, \dots, |I(\vartheta)|\} \rightarrow I(\vartheta).$$

Let the maps

$$I', J' : \{1, \dots, |\vartheta|\} \rightarrow \{1, \dots, |I(\vartheta)|\}$$

be defined by $I'(i) := p^{-1}(I(n(i)))$, $J'(i) := p^{-1}(J(n(i)))$. Then $f(E_\bullet^{I'}) = E_\bullet^{I'}$ and $f(E_\bullet^{J'}) = E_\bullet^{J'}$. Since f is $\text{GL}(\Theta)$ -equivariant, $f(R') = R$, and $f(W') \subseteq W$. \square

Corollary 3.4 $df(TW') \subseteq TW$ is a subbundle.

We will use the following theorem to determine triviality of $\nu(W)|_R$.

Theorem 3.5 $TW|_R$ is an inner direct sum of the subbundles $\{\lambda_{cd} : (c, d) \in T_I\}$ where λ_{cd} are defined in (3.3). $\nu(W)|_R$ is isomorphic to $\bigoplus_{(c,d) \in N_I} \lambda_{cd}$.

We split the proof of Theorem 3.5 into several parts. First, we prove Proposition 3.6, whose Corollaries 3.7, 3.8 are exactly the statement of Theorem 3.5.

Proposition 3.6 $\{\lambda_{cd} : (c, d) \in T_I\}$ are subbundles of $TW|_R$, where λ_{cd} are defined in (3.3).

Proof Let $(c, d) \in T_I$ and set $\vartheta = \{a, b, c, d\}$ as above, $\vartheta_1 = \{a, b\}$ and $\vartheta_2 = \vartheta \setminus \vartheta_1$ (this has either 1 or 2 elements).

If $|\vartheta| = 4$, then by Proposition 2.3 $(c, d) \in T_J$. In this case we can further decompose \mathcal{D}_1 as

$$(\mathcal{D}_{1i})_\kappa = |\{k \in \vartheta_i : I(k) = \kappa\}|, \quad \kappa = 1, \dots, m$$

$\mathcal{D}_1 = \mathcal{D}_{11} + \mathcal{D}_{12}$ and $\Theta = \Theta_1 \oplus \Theta_2$ for $\Theta_i = \langle \varepsilon_k : k \in \vartheta_i \rangle$. Note that $\mathcal{D}_{1i} = (1, 1)$, $(i = 1, 2)$ in the appropriate positions. This decomposition induces another direct sum map

$$g : \mathbb{P}\Theta_1 \times \mathbb{P}\Theta_2 \rightarrow \text{Fl}_{\mathcal{D}_1}(\Theta).$$

Let $W'' := \mathbb{P}\Theta_1 \times (\mathbb{P}\Theta_2 \setminus \mathbb{P}\varepsilon_d)$ and $R'' := \mathbb{P}\Theta_1 \times \mathbb{P}\varepsilon_c$. As in the proof of Proposition 3.3, equivariance shows that $W' := \Omega_{I'} \cup \Omega_{J'} = g(W'')$ and $R' = g(R'')$. Then $\varepsilon_{cd} \subseteq TW''|_{R''}$. Applying Proposition 2.4 for g and f ,

$$\lambda_{cd} = d(f \circ g)\varepsilon_{cd} \subseteq TW|_R.$$

If $|\vartheta| = 3$, we are in the case of $\mathcal{D}_1 = (1, 1, 1)$, $\mathcal{D}_1 = (2, 1)$ or $\mathcal{D}_1 = (1, 2)$. Then Table 1 shows that the Proposition holds for $I', J' \in \binom{3}{\mathcal{D}_1}$ and $(c', d') \in T_{I'}$. By Proposition 2.4, $\lambda_{cd} \subseteq TW|_R$. □

Corollary 3.7 The subbundles $\{\lambda_{cd} : (c, d) \in T_I\}$ are linearly independent and therefore span $TW|_R$.

Proof Set $\vartheta_1 = \{a, b\}$ and $\Theta_1 = \varepsilon_a \oplus \varepsilon_b$. It is enough to show that the bundles λ_{cd} are linearly independent in each summand

$$\text{End}(\mathbb{R}^N) = \text{End}(\Theta_1^\vee) \oplus \text{End}(\Theta_1) \oplus \bigoplus_{k \neq a, b} (\text{Hom}(\Theta_1, \varepsilon_k) \oplus \text{Hom}(\varepsilon_k, \Theta_1))$$

Given c, d , set $\vartheta = \{a, b, c, d\}$, $\vartheta_2 = \vartheta \setminus \vartheta_1$, and $\Theta_2 = \langle \varepsilon_k : k \in \vartheta_2 \rangle$.

If $|\vartheta| = 4$, then $\lambda_{cd} = \varepsilon_{cd}$ which are linearly independent in $\text{End}(\Theta_1^\vee)$.

If $|\vartheta| = 3$, then $|\vartheta_2| = 1$, denote its single element by k . Then

$$\lambda_{cd} \subseteq \text{Hom}(\Theta_1, \varepsilon_k) \oplus \text{Hom}(\varepsilon_k, \Theta_1)$$

For fixed k there are at most 2 such (c, d) pairs, since $c > d$ for $(c, d) \in T_I$. So it is enough to check linear independence of such pairs.

If $a > k > b$, then $\lambda_{ak} \subseteq \text{Hom}(\Theta_1, \varepsilon_k)$, $\lambda_{kb} \subseteq \text{Hom}(\varepsilon_k, \Theta_1)$, so they are independent.

If $a > b > k$ then in order for $(a, k), (b, k) \in T_I$ to hold, $I(a) < I(b) < I(k)$ must hold, then $\lambda_{ak} = \varepsilon_{ak}, \lambda_{bk} = \varepsilon_{bk}$ are independent in $\text{Hom}(\Theta_1, \varepsilon_k)$. The case $k > a > b$ is similar.

Finally, $\lambda_{ab} = \text{Hom}(\rho, \rho^\vee) \subseteq \text{End}(\Theta_1)$. □

Corollary 3.8 $\nu(W)|_R$ is isomorphic to $\bigoplus_{(c,d) \in N_I} \lambda_{cd}$.

This concludes the proof of Theorem 3.5. Let us introduce some notation.

Definition 3.9 Fix $I \in \text{OSP}(\mathcal{D})$, $\mathcal{D} = (d_1, \dots, d_m)$, and fix $a, b \in \{1, \dots, N\}$ such that $\alpha = I(a), \beta = I(b), \alpha < \beta$. For $c \in \{1, \dots, N\}, \gamma, \delta \in \{0, 1, \dots, m\}$, set

$$\begin{aligned} G_I(c, \gamma, \delta) &:= |\{d > c : \gamma < I(d) \leq \delta\}|, \\ L_I(c, \gamma, \delta) &:= |\{d < c : \gamma < I(d) \leq \delta\}| \\ T_I(a, b) &:= L_I(a, \alpha, \beta) + G_I(b, \alpha - 1, \beta - 1), \\ N_I(a, b) &:= G_I(a, \alpha, \beta) + L_I(b, \alpha - 1, \beta - 1) \\ G_I(a, \delta) &:= G_I(a, \delta, m), \quad G_I(a) := G_I(a, \alpha), \end{aligned} \tag{3.5}$$

abbreviating Greater, Less, Tangent, Normal.

We will be interested in these numbers for the fixed adjacent $J \leq I \in \text{OSP}(\mathcal{D})$, where J is obtained by interchanging $a \in I_\alpha$ with some $b \in I_\beta, a > b, \alpha < \beta$. Note that by Definition (3.3) of $\lambda_{cd}, N_I(a, b)$ is the number of nontrivial λ_{cd} for $(c, d) \in N_I$. Then by Proposition 3.1 and Theorem 3.5, we have:

Theorem 3.10 If $I, J \in \text{OSP}(\mathcal{D}), \ell(J) = \ell(I) - 1$ and J is obtained from I by interchanging $a \in I_\alpha$ with some $b \in I_\beta, a > b, \alpha < \beta$, then using the notations (3.5):

$$[\Omega_I, \Omega_J] = \begin{cases} 0, & \text{if } N_I(a, b) \text{ is even} \\ \pm 2, & \text{if } N_I(a, b) \text{ is odd} \end{cases} \tag{3.6}$$

Example 3.11 Let us compute the incidence coefficient $[\Omega_I, \Omega_J]$ up to sign for

$$I = [3\ 6, 1\ 4, 2\ 5], \quad J = [2\ 6, 1\ 4, 3\ 5]$$

in $\text{Fl}_{2,2,2}$ (recall the notation introduced after (2.1)). In this case $a = 3, \alpha = 1, b = 2, \beta = 3$. There are two elements in $I_2 \cup I_3$ (4 and 5) greater than $a = 3$, so $G_I(a, \alpha, \beta) = 2$. There is one element in $I_1 \cup I_2$ which is less than $b = 2$, so $L_I(a, \alpha, \beta) = 1$, thus $N_I(a, b) = 3$ and $[\Omega_I, \Omega_J] = \pm 2$.

To any cochain complex, one can define an *incidence graph* as was done in [12]: the vertices of the graph are elements of $\binom{N}{\mathcal{D}}$ and (I, J) is an edge iff $[\Omega_I, \Omega_J] \neq 0$. See Fig. 3 for the incidence graph of $\text{Fl}(\mathbb{R}^4)$ at the end of this section (the colors correspond to the signs).

Fig. 2 The double of a Young diagram

3.7 Determining the cycles

In the even case $\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}$, equation (3.6) is actually sufficient to determine the rational coefficient cohomology $H^*(\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$ additively in terms of Schubert cycles, i.e. the sign of ± 2 can be ignored. For the \mathbb{Z} -coefficient cohomology, the signs are required as well, see Sect. 3.9.

If $2\mathcal{D} = (2d_1, 2d_2, \dots, 2d_r)$ and $I \in \text{OSP}(\mathcal{D})$, then the doubled ordered set partition $DI \in \text{OSP}(2\mathcal{D})$ is obtained by replacing each $i \in I_j$ by $(2i - 1, 2i) \in DI_j$; each element $k \in DI_j$ has a unique pair $k' \in DI_j$. A double Schubert variety $\sigma_{DI}^{\mathbb{R}} \subseteq \text{Fl}_{2\mathcal{D}}^{\mathbb{R}}$ is a Schubert variety corresponding to $DI \in \text{OSP}(2\mathcal{D})$.

In the case of Grassmannians $\mathcal{D} = (k, l)$, $DI \in \binom{2(k+l)}{2k}$ we recover the double Young diagrams of Pontryagin [44], see also [23, III.3.2.2.B] and [20, Theorem 3.3.1]. These Young diagrams are obtained by subdividing each square into 2×2 squares in the Young diagram corresponding to $I \in \binom{k+l}{k}$, see Fig. 2. In terms of ordered set partitions, for $\mathcal{D} = (1, 1)$, the doubled ordered set partitions are $[1\ 2, 3\ 4]$ and $[3\ 4, 1\ 2] \in \text{OSP}(2\mathcal{D})$, which are the doubles of $[1, 2]$ and $[2, 1] \in \text{OSP}(\mathcal{D})$ respectively.

Theorem 3.12 *In $\text{Fl}_{2\mathcal{D}}(\mathbb{R}^N)$ the double Schubert varieties σ_{DI} are (integer) cycles and their classes $[\sigma_{DI}]$ generate a free \mathbb{Z} -submodule of $H^*(\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}; \mathbb{Z})$. Rationally, $[\sigma_{DI}]$ form a basis of $H^*(\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$.*

Proof Let $I = DI' \in \text{OSP}(2\mathcal{D})$ be a doubled ordered set partition. As above, if $\Omega_J \subseteq \sigma_I$ and $\ell(I) - \ell(J) = 1$, then J is obtained by interchanging $a \in I_\alpha$ with some $b \in I_\beta$, $\alpha < \beta$, $a > b$. Since I is doubled, both terms in the sum

$$N_I(a, b) = G_I(a, \alpha, \beta) + L_I(b, \alpha - 1, \beta - 1) \tag{3.7}$$

are even; e.g. if $k > a$ and $I(k) > \alpha$, then its pair k' also satisfies $k' > a$ and $I(k') = I(k) > \alpha$. So all coefficients $[\Omega_I, \Omega_J]$ vanish and σ_I is a cycle.

Now assume that $\Omega_I \subseteq \sigma_J$ and $\ell(J) - \ell(I) = 1$, and $I = DI'$ be obtained by interchanging $a \in J_\alpha$ with some $b \in J_\beta$, $\alpha < \beta$, $a > b$. We again have to determine the parity of (3.7), but now for $N_J(a, b)$. Let a' and b' denote the pairs of a and b respectively. Since I is a doubled ordered set partition, $a' \in I_\beta$ and $b' \in I_\alpha$. $\ell(J) - \ell(I) = 1$ implies that $a < a'$ and $b' < b$. As before, everything in J appears in pairs, except $a < a'$ and $b < b'$ which shows that $G_J(a, \alpha, \beta)$ and $L_J(a, \alpha - 1, \beta - 1)$ are both odd. So $N_J(a, b)$ is even and Ω_I appears in all incidence relations with zero coefficient $[\Omega_J, \Omega_I] = 0$. Therefore $[\sigma_I]$ does not appear in any relation and the double Schubert cycles $\{[\sigma_{DJ}] : J \in \text{OSP}(\mathcal{D})\}$ are linearly independent.

Finally, $\dim_{\mathbb{Q}} H^*(\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}; \mathbb{Q}) = |\text{OSP}(\mathcal{D})|$, which follows e.g. from Theorem A.3. This agrees with the number of doubled ordered set partitions of $2\mathcal{D}$. □

3.8 Kocherlakota’s theorem

Theorem 3.10 gives an alternate proof of Kocherlakota’s theorem [38, Theorem A] for the special case of the classical real flag manifolds $Fl_{\mathcal{D}}^{\mathbb{R}}$. Before stating it we have to introduce some further notation.

Let \mathfrak{g} be a real split semisimple Lie algebra. Let \mathfrak{a} be a maximal \mathbb{R} -diagonalizable subalgebra and let $\Sigma \subseteq \mathfrak{a}^*$ be the restricted root system. Since \mathfrak{g} is split, all root multiplicities are one. Choose a regular element $\xi \in \mathfrak{a}$, which determines a positive Weyl chamber C^+ and $\Sigma = \Sigma^+ \amalg \Sigma^-$. The reflections r_φ in the root planes $\ker \varphi$, $\varphi \in \Sigma^+$ generate the Weyl group W of the root system. The Weyl group acts freely and transitively on the Weyl chambers, and the Weyl chambers C_w are labeled by $w \in W$, $C^+ = C_1$ for $1 \in W$. Given $H \in \overline{C^+}$, let $\Theta \subseteq \Sigma^s$ be the set of simple roots vanishing at H . Then the Weyl orbit $W.H = W/W_H$ parametrizes the Bruhat cells of G/P_Θ (cf. [15]). Now we state Kocherlakota’s theorem. Given $x \in \mathfrak{a}$, let

$$\begin{aligned} \mathcal{N}(x) &:= \{ \varphi \in \Sigma^+ : \varphi(x) < 0 \}, \\ \sigma(x) &:= \sum_{\varphi \in \mathcal{N}(x)} \varphi \in \mathfrak{a}^*, \end{aligned}$$

and $\ell(x) := |\mathcal{N}(x)|$ (we change the notation of Kocherlakota to \mathcal{N} in order to distinguish from N_I). This is consistent with notation (2.4), as we will show below, and in general it is the dimension of $\Omega_x \subseteq G/P_\Theta$ for $x \in W.H$. We will give another interpretation of $\mathcal{N}(x)$, see (3.8). Let us now recall the theorem of Kocherlakota.

Theorem 3.13 (Kocherlakota) *Let $x, y \in W.H = W/W_H$ and $\ell(y) = \ell(x) - 1$. If $r_\varphi(x) = y$ for a reflection r_φ , $\varphi \in \Sigma^+$, then $\sigma(x) - \sigma(y) = m\varphi$ for some $m \in \mathbb{Z}$. The incidence coefficients of the Bruhat cells Ω_x, Ω_y are given by*

$$[\Omega_x, \Omega_y] = \begin{cases} 0, & m \text{ odd} \\ \pm 2, & m \text{ even} \end{cases}$$

Before giving the proof for $\mathfrak{g} = \mathfrak{sl}(N, \mathbb{R})$, let us recall some specifics about the root system of type A_{N-1} . The roots in an appropriate basis are $\pm e_{ij}$ where $e_{ij} = e_i - e_j$, $i < j$. The simple roots are $\delta_i = e_{i,i+1}$, and in terms of the simple roots $e_{ij} = \sum_{k=i}^j \delta_k$. Its Weyl group is $W \cong S_N$ and the reflections r_{ij} through the hyperplane $\ker e_{ij}$ correspond to the transpositions $(ij) \in S_N$.

The Weyl-orbit of a regular element $H \in C^+$ can be parametrized by $W \cong S_N$. If $H \in \overline{C^+}$ is not regular, list the simple roots δ_i not vanishing on H : $\delta_{s_1}, \delta_{s_2}, \dots, \delta_{s_r}$, such that $s_1 < s_2 < \dots < s_r$, and set $s_{r+1} := N$. Then the Weyl-orbit $W.H = W/W_H = \text{OSP}(\mathcal{D})$, where $\mathcal{D} = (d_1, \dots, d_r)$, for $d_i = s_{i+1} - s_i$.

This implies that positive roots $e_{ij} \in \Sigma^+$ have the following property: given $I \in W/W_H$, $e_{ij}(I) < 0$ iff (i, j) is an inversion of $I \in W/W_H$. Thus $\mathcal{N}(I)$ is the set of inversions of $I \in W/W_H$:

$$\mathcal{N}(I) = \{ e_{ij} : (i, j) \text{ is an inversion of } I \} \tag{3.8}$$

In particular, for $I \in \text{OSP}(\mathcal{D})$, $|\mathcal{N}(I)| = \ell(I) = \dim_{\mathbb{R}} \Omega_I$ as we have stated above (e.g. by Proposition 2.3).

Proof (Proof of Theorem 3.13 for $\mathfrak{g} = \mathfrak{sl}(N, \mathbb{R})$) Let $I, J \in W/W_H = \text{OSP}(\mathcal{D})$, such that $r_{ab}(I) = J$, and $\ell(J) = \ell(I) - 1$, $a > b$, $a \in I_\alpha, b \in I_\beta$. By (3.8), the set theoretic difference of $\mathcal{N}(J) \setminus \mathcal{N}(I)$ consists of those e_{ij} , for which i, j is an inversion in J , but not in I .

Clearly all such i, j pairs must contain a or b . A simple verification shows that there are three types of elements in $\mathcal{N}(I) \setminus \mathcal{N}(J)$ (the other cases can be excluded using $\ell(J) = \ell(I) - 1$):

- If $e_{bj} \in \mathcal{N}(I) \setminus \mathcal{N}(J)$ and $a < j$, then $e_{aj} \in \mathcal{N}(J) \setminus \mathcal{N}(I)$,
- if $e_{ja} \in \mathcal{N}(I) \setminus \mathcal{N}(J)$ and $j < b$, then $e_{jb} \in \mathcal{N}(J) \setminus \mathcal{N}(I)$, and
- $e_{ba} \in \mathcal{N}(I) \setminus \mathcal{N}(J)$.

Since $e_{bj} - e_{aj} = e_{ba}$ for $b < a < j$ and $e_{ja} - e_{jb} = e_{ba}$ for $j < b < a$

$$\begin{aligned} \sigma(I) - \sigma(J) &= \sum_{e_{ij} \in \mathcal{N}(I) \setminus \mathcal{N}(J)} e_{ij} - \sum_{e_{ij} \in \mathcal{N}(J) \setminus \mathcal{N}(I)} e_{ij} \\ &= (G_I(a, \alpha, \beta) + L_I(b, \alpha - 1, \beta - 1) + 1) e_{ba} = (N_I(a, b) + 1) e_{ba} \end{aligned}$$

using the definitions preceding Theorem 3.10. We can conclude by Theorem 3.10. \square

3.9 Signs

For cooriented Ω_I and Ω_J , determining the actual signs of $[\Omega_I, \Omega_J]$ requires some further work. We conclude this section by determining the signs. We obtain similar results as [46] who deal with the general case of R -spaces. One can make several choices of orientations - we coorient all Ω_I lexicographically as described in Section 3.1 and compute the signs of $[\Omega_I, \Omega_J]$ relative to these orientations.

3.9.1 Geometry

Before stating the following Proposition describing the signs, let us introduce some notation. Let $I, J \in \text{OSP}(\mathcal{D})$ be adjacent, obtained by swapping $a \in I_\alpha$ with some $b \in I_\beta$. We will denote by $(e_c \mapsto e_d) \in \text{Hom}(\varepsilon_c, \varepsilon_d)$ the homomorphism mapping e_c to e_d . Let R_+ be a branch of the Richardson curve R and let U be a slight enlargement of R_+ : a (contractible) connected open set $U \subsetneq R$ containing $\overline{R_+}$. Let $r \in \Gamma(\rho|_U)$ and $r^\vee \in \Gamma(\rho^\vee|_U)$ be nowhere vanishing sections, such that $r(I) = -r^\vee(J) = e_a$ and $r^\vee(I) = r(J) = e_b$ (this choice determines the branch R_+). Define sections of $\lambda_{cd}|_U$, for $(c, d) \in N_I$ as follows:

$$s_{cd} := \begin{cases} (e_c \mapsto e_d), & \text{if } (c, d) \in N_J \\ (r \mapsto e_d), & \text{if } c = a, I(a) < I(d) \leq I(b) \\ (e_c \mapsto r^\vee), & \text{if } d = b, I(a) \leq I(c) < I(b) \end{cases}$$

These are the only cases that appear in (3.3) for $(c, d) \in N_I$, since $(a, b) \in T_I$. We will say that s_{cd} is *trivial* if $s_{cd} = (e_c \mapsto e_d)$ and *nontrivial* otherwise. Notice that s_{cd} is trivial iff $(c, d) \in N_I$ and $(c, d) \in N_J$.

Proposition 3.14 *The sign of $[\Omega_I, \Omega_J]$ is $+1$ iff the following two orientations agree, -1 otherwise:*

$$N_J^1 := ((e_c \mapsto e_d) : (c, d) \in N_J), \quad N_J^2 := (- (e_b \mapsto e_a), s_{cd}(J) : (c, d) \in N_J)$$

where in both N_J^1 and N_J^2 , the terms involving (c, d) are listed lexicographically.

Proof Recall that the incidence coefficient $[\Omega_I, \Omega_J]$ in the Vassiliev complex can be computed as a sum of ± 1 contributions for each branch R_\pm of the Richardson curve (cf. Sect. 2.1). The contribution of one of the branches R_+ can be computed as follows. Take the splitting

$$TB^-J|_{R_+} = TR \oplus \nu_I|_{R_+}, \tag{3.9}$$

where ν_I is the sum of line bundles of Theorem 3.5. Then the contribution of R_+ is obtained by comparing the following two orientations of TJB^-J :

- the orientation induced by the coorientation of $\nu(\Omega_J)|_J$: this is the lexicographical orientation $N_J^1 = ((e_c \mapsto e_d) : (c, d) \in N_J)$ and
- the orientation O_2 determined by the splitting (3.9): $TR|_{R_+}$ is oriented towards J , and $\nu_I|_{R_+}$ is oriented by the coorientation of Ω_I .

Note that the second orientation has to be extended to J . In order to extend the orientation of $TB^-J|_{R_+}$ to J , we will use the sections s_{cd} : if the orientation $(s_{cd}(I))$ agrees with the coorientation Ω_I , then the orientation $(TR|_U, s_{cd}(J))$ determines the orientation O_2 . On the branch R_+ , $(r \mapsto r^\vee)$ points towards J , so O_2 is exactly N_J^2 . □

Therefore the combinatorial task is to determine the (relative) sign of two signed permutations.

3.9.2 Combinatorics

Before giving a notation heavy answer, let us illustrate on a simple example the computation of the signs:

Example 3.15 Let $\mathcal{D} = (1^6)$, $I = (4, 5, 6, 1, 2, 3)$ and $J = (4, 2, 6, 1, 5, 3)$, so $a = 5$, $b = 2$, $\alpha = 2$, $\beta = 5$. The normal spaces in lexicographical ordering are spanned by

$$N_I = (12)(13)(23)(45)(46)(56), \quad N_J = (13)(15)(23)(25)(26)(45)(46)$$

where (ij) denotes $\pm(e_i \mapsto e_j)$ (recall the description of the normal spaces in Proposition 2.3). One has to compare two orientations of $N_J\Omega_J$, the first orientation being the lexicographical orientation N_J^1 . The second orientation is given by

$N_J^2 = ((ba), N_I(a \leftrightarrow b))$, where $a \leftrightarrow b$ is the operation of exchanging a and b in (cd) ($\{c, d\} \cap \{a, b\} \neq \emptyset$) if s_{cd} is a nontrivial section (i.e. if (cd) appears only in N_I). These orientations here are (notice that $(2, 3)$ appears in both N_I and N_J , so s_{23} is trivial and there is no substitution $2 \leftrightarrow 5$ for (23)):

$$N_J^1 = (13)(15)(23)(25)(26)(45)(46), \quad N_J^2 = (25)(15)(13)(23)(45)(46)(26).$$

The first difference c_1 comes from listing $(ab) = (25)$ first in N_J^2 , this contributes $c_1 = 3$ transpositions: it precedes $(13)(15)(23)$. The second difference c_2 comes from exchanging (a, d) with (b, d) if $(a, d) \notin N_J$; this contributes $c_2 = 2$ as (26) succeeds $(45)(46)$. The third difference c_3 comes from exchanging all (c, b) with (c, a) if $(c, b) \notin N_J$; this contributes $c_3 = 1$ transpositions; (15) precedes (13) . Finally, the nontrivial sections involving $r^\vee(J) = -e_5$ obtain a sign: this contributes $c_4 = 2$ sign changes, $-(e_1 \mapsto e_5) \in \text{Hom}(e_1, \rho^\vee)|_J$ and $-(e_2 \mapsto e_5)$. So the incidence coefficient is $[I, J] = (-1)^8 2 = +2$, where $c_1 + c_2 + c_3 + c_4 = 8$.

The following Theorem formalizes this computation:

Theorem 3.16 *If $[\Omega_I, \Omega_J] \neq 0$, then its sign is given by $[\Omega_I, \Omega_J] = (-1)^{s(I, J)} \cdot 2$, where*

$$s(I, J) = c_1 + c_2 + c_3 + c_4$$

and using the notations of Definition 3.9, the c_i are defined as follows:

$$\begin{aligned} c_1 &= G_I(b, \alpha) - G_I(a) + \sum_{c < b} G_I(c) \\ c_2 &= (G_I(a) - G_I(a, \beta)) \left(\sum_{b < c < a} G_I(c) + G_I(a, \beta) \right) \\ c_3 &= \sum_{\substack{c < b \\ \alpha \leq I(c) < \beta}} G_I(b, I(c)) - G_I(a, I(c)) \\ c_4 &= L_I(b, \alpha - 1, \beta - 1) + 1 \end{aligned}$$

Proof The first permutation is the elements of N_J^1 listed lexicographically:

$$\begin{aligned} &\dots, (b - 1, d_{n_{b-1}}^{b-1}), (b, d_1^b), \dots, (b, a), \dots, (b, d_{n_b}^b), \dots, (c, d_1^c), \dots, (c, d_{n_c}^c) \\ &\dots, (a, d_1^a), \dots, (a, d_{n_a}^a), \dots \end{aligned}$$

The second permutation is obtained by listing (b, a) and then the elements of N_I lexicographically

$$\begin{aligned} &(b, a), \dots, (b - 1, f_{m_{b-1}}^{b-1}), (b, f_1^b), \dots, (b, f_{m_b}^b), \\ &\dots, (c, f_1^c), \dots, (c, f_{m_c}^c), \dots, (a, f_1^a), \dots, (a, f_{m_a}^a), \dots \end{aligned}$$

and making the following substitutions, which compared to N_J^1 contribute a certain number of transpositions that we will determine below:

- listing (b, a) first: this contributes c_1 many transpositions,
- replacing (a, d) with (b, d) for all nontrivial sections s_{ad} : c_2 many transpositions,
- replacing (c, b) with (c, a) for all nontrivial sections s_{cd} : c_3 many transpositions.

One must also count the sign differences coming from the values of $s_{cd}(J) = \pm(e_c \mapsto e_d)$. These sign differences are represented by the term c_4 . Now we determine c_1, c_2, c_3, c_4 .

The first difference is that $(e_b \mapsto e_a)$ is the first element in N_J^2 . This contributes

$$c_1 = |\{b < c < a : J(b) < J(c)\}| + \sum_{c < b} G_I(c) = G_I(b, \alpha) - G_I(a) + \sum_{c < b} G_I(c)$$

many transpositions.

Given a nontrivial section $s_{ad}, (a, d) \in N_I: s_{ad}(J) = \pm(e_b \mapsto e_d)$, it has the following distance from its final position at (b, d) in $N_J^1: (a > b)$

$$\begin{aligned} &|\{a < c < d : I(b) < I(c)\}| + |\{d < c : I(b) < I(c)\}| + \sum_{b < c < a} G_I(c) = \\ &= G_I(a, \beta) - G_I(d, \beta) + G_I(d, \beta) + \sum_{b < c < a} G_I(c) \end{aligned}$$

as $(e_a \mapsto e_d)$ swaps place with every $(e_f \mapsto e_g)$ pair whose position doesn't change and precedes it. The sum of these for nontrivial s_{ad} pairs is the term c_2 .

Similarly, for a nontrivial section $s_{cb}, (c, b) \in N_I, s_{cb}(J) = \pm(e_c \mapsto e_a)$ has the following distance from its final position:

$$|\{b < d < a : I(c) < I(d)\}| = G_I(b, I(c)) - G_I(a, I(c))$$

the sum of which for nontrivial s_{cb} pairs is c_3 .

Finally, the sections s_{cd} induce $L_I(b, \alpha - 1, \beta - 1) + 1$ many sign changes: the trivial bundles have trivial sections, the nontrivial sections s_{cd} involving only r introduce no sign change, whereas each bundle involving $r^\vee(J) = -e_a$ contributes a sign change, the number of which is $c_4 = L_I(b, \alpha - 1, \beta - 1) + 1$. □

Remark 3.17 The sign of $[\Omega_I, \Omega_J]$ determines a coloring of the incidence graph (see Fig. 3). Taking the opposite orientation of a vertex I , changes the color of all edges incident to I , however since in the end such a graph computes the cohomology of $\text{Fl}_{\mathcal{D}}$, the cohomology of the chain complex is the same.

For another choice of orientations, see [46]. There a reduced decomposition $w = r_1 \dots r_d$ is fixed for each $w \in S_N$, and such a reduced decomposition determines an ordering of the inversions of w , i.e. an orientation of T_I . Such an ordering is convenient, since for adjacent $w' < w = r_1 \dots r_d, w'$ has a reduced decomposition obtained by omitting some uniquely defined r_i - then the relative orientation

Fig. 3 The signed incidence graph of Fl_4 : blue (dashed) edges signify $+2$, red (solid) edges -2

of $r_i, r_1, \dots, \hat{r}_i, \dots, r_d$ and r_1, \dots, r_d is simply $(-1)^i$. However, the initially fixed reduced decomposition of w' might differ from $r_1 \dots \hat{r}_i \dots r_d$, so one also has a term comparing these two orientations.

The signs obtained in Theorem 3.16 can be implemented in a computer program, and can be used to compute the cohomology groups of real flag manifolds with integer coefficients. We were mainly interested in the Schubert cycle generators of rational coefficient cohomology. We used SageMath’s homology package [52]. See Appendix B for results in some cases not covered by Theorem 3.12.

3.10 An example $Fl(\mathbb{R}^4)$

Figure 3 contains the incidence graph of $Fl(\mathbb{R}^4)$ defined as follows. The vertices of the graph are the Schubert cells $X_\alpha, \alpha \in S_4$ and two vertices X_α, X_β are connected by an edge if $[X_\alpha, X_\beta] = \pm 2$. This diagram can also be found in [12, p. 529]. The extra information is the coloring of the graph representing the signs: a blue (dashed) edge represents $[\Omega_I, \Omega_J] = +2$ a red (solid) edge corresponds to -2 . In this case, in order to compute the cohomology, the signs are actually not needed, as can be seen from the form of the graph; one can read off the cohomology groups of $Fl(\mathbb{R}^4)$:

$$\begin{aligned}
 H^0 &= \mathbb{Z}, & H^1 &= 0, & H^2 &= \mathbb{Z}_2^{\oplus 3}, & H^3 &= \mathbb{Z}^{\oplus 2} \oplus \mathbb{Z}_2^{\oplus 2}, & H^4 &= \mathbb{Z}_2^{\oplus 2}, \\
 H^5 &= \mathbb{Z}_2^{\oplus 3}, & H^6 &= \mathbb{Z}
 \end{aligned}$$

The generators of the cohomology groups are not necessarily unique: $x = 1432$ and $y = 3214$ generate a submodule isomorphic to $\mathbb{Z} \oplus \mathbb{Z}_2$ – their sum is a 2-torsion element, whereas either of them generates a free \mathbb{Z} -submodule. The smallest instance

where we encountered a possible dependence on the choice of the signs is $\text{Fl}(\mathbb{R}^6)$: by changing the signs so that the incidence graph still defines a chain complex, the cohomology groups can be different. Therefore the signs are indeed required in certain cases.

4 The ring structure of $H^*(\text{Fl}_{2D}^{\mathbb{R}}; \mathbb{Q})$: Schubert calculus

The double Schubert varieties $\sigma_{DI}^{\mathbb{R}}$ are cycles and their classes form a basis of $H^*(\text{Fl}_{2D}^{\mathbb{R}}; \mathbb{Q})$ by Theorem 3.12. By showing that $\text{Fl}_{2D}^{\mathbb{R}}$ are *circle spaces* [17,41] we can deduce their structure constants by relating them to the structure constants of Schubert cycles in complex flag manifolds. Our main tool is Theorem 4.2, the *generalized Borel-Haefliger theorem*, [17]. Applying this theorem, we obtain that any formula involving Schubert cycles $[\sigma_I^{\mathbb{C}}]$ in a complex partial flag manifold $\text{Fl}_D^{\mathbb{C}}$, holds for the doubled real Schubert cycles $[\sigma_{DI}^{\mathbb{R}}]$ in the double real partial flag manifold $\text{Fl}_{2D}^{\mathbb{R}}$.

Circle spaces are analogues of conjugation spaces introduced by Hausmann, Holm and Puppe [29]. The \mathbb{Z}_2 -actions are replaced by $U(1)$ -actions, and \mathbb{F}_2 -coefficient cohomology is replaced by \mathbb{Q} -coefficient cohomology. In the following set $\Gamma := U(1)$. Given a Γ -space X , denote by X^Γ the set of Γ -fixed points and denote the Γ -equivariant cohomology of X by

$$H_\Gamma^*(X) = H^*(B_\Gamma X; \mathbb{Q}), \quad \text{and} \quad H_\Gamma^* = H^*(\mathbb{C}P^\infty; \mathbb{Q}) = \mathbb{Q}[u],$$

where u is the Euler class of the dual tautological bundle over $\mathbb{C}P^\infty$. We briefly recall the definition and main properties of circle spaces, and for further details we refer to [17] and [41].

Definition 4.1 A Γ -space X is a *circle space*, if

- X has nonzero cohomology in degrees $4i$,
- there exists a degree-halving additive isomorphism $\kappa : H^{2*}(X) \rightarrow H^*(X^\Gamma)$,
- there exists a Leray-Hirsch section (also known as cohomology extension of the fiber) $\sigma : H^*(X) \rightarrow H_\Gamma^*(X)$ which is multiplicative, and satisfies the *restriction equation*: for any $x \in H^{4d}(X)$:

$$r(\sigma(x)) = \kappa(x)u^d + \eta$$

where $r : H_\Gamma^*(X) \rightarrow H_\Gamma^*(X^\Gamma) \cong H^*(X^\Gamma)[u]$, and η is a u -polynomial of degree less than d .

Given a circle space X , it satisfies the following properties:

- κ and σ are multiplicative,
- a pair (κ, σ) satisfying the restriction equation is unique, and they satisfy a naturality property with respect to equivariant maps between circle spaces.

Before stating the generalized Borel-Haefliger theorem we have to introduce a technical definition. By a *good Γ -invariant cycle* $Z \subseteq X$ we mean that

- Z is a Γ -invariant stratified submanifold which is a cycle,
- its top stratum Z_k is Γ -invariant,
- the fixed point set Z^Γ has a stratification with unique, connected top stratum Z_k^Γ of some codimension $2l$.

These technical conditions ensure that Z^Γ is also a cycle, and that

$$[Z \subseteq X]_{\Gamma|_{X^\Gamma}} = w \cdot [Z^\Gamma \subseteq X^\Gamma] + \eta$$

in $H_\Gamma^*(X^\Gamma) \cong H^*(X^\Gamma)[u]$, where $w = w_0 \cdot u^l$, $w_0 \in \mathbb{Z}$ is the weight of a representation and η is a sum of u -monomials of degree less than l . This can be shown via the Excess Intersection Formula [45]. If $Z \subseteq X$ is a good Γ -invariant cycle satisfying $\text{codim } Z \subseteq X = 2 \text{ codim } Z^\Gamma \subseteq X^\Gamma$, then we say in short that Z is a *halving cycle*. To show that a space is a circle space, we can apply the following theorem [17, Theorem 4.1]:

Theorem 4.2 (Generalized Borel-Haefliger theorem) *Let $\Gamma = \text{U}(1)$ and let X be a compact oriented manifold with a smooth Γ -action, whose rational cohomology groups have a basis of halving cycles $[Z_i] \in H^{4k_i}(X)$. Assume that the Γ -equivariant normal bundle $\nu(X^\Gamma \hookrightarrow X)$ has only one weight $\lambda \in \mathbb{Z}$. Then X is a circle space with $\kappa[Z_i] = \lambda^{k_i}[Z_i^\Gamma]$ and $\sigma[Z_i] = [Z_i]_\Gamma$.*

In particular, the assignment sending $[Z_i]$ to $[Z_i^\Gamma]$ determines a degree-halving multiplicative isomorphism between $H^{2}(X; \mathbb{Q})$ and $H^*(X^\Gamma; \mathbb{Q})$.*

Remark 4.3 More generally, one can drop the assumption on orientability [17, Remark 3.24] and only assume that X and X^Γ satisfy \mathbb{Q} -Poincaré duality [1, Definition 5.1.1] and that their formal dimensions satisfy $\text{fd}(X) = 2 \text{ fd}(X^\Gamma)$. (X is a \mathbb{Q} -Poincaré duality space if $H^{\text{top}}(X; \mathbb{Q}) \cong \mathbb{Q}$ and the pairing $H^k(X) \otimes H^{\text{top}-k}(X) \rightarrow H^{\text{top}}(X)$ is perfect; $\text{fd}(X) := \text{top degree}$.)

Our main examples of circle spaces are the real even flag manifolds $\text{Fl}_{2\mathcal{D}}^\mathbb{R}$. Introduce a Γ -action on real flag manifolds in \mathbb{R}^{2n} as follows: The identification of $\mathbb{R}^{2n} \leftrightarrow \mathbb{C}^n$ as real Γ -representations induces an action on $\text{Fl}_\mathcal{E}(\mathbb{R}^{2n})$, $\mathcal{E} = (e_1, \dots, e_r)$.

Theorem 4.4 *Let $\Gamma := \text{U}(1)$. With the Γ -action introduced above, $\text{Fl}_{2\mathcal{D}}(\mathbb{R}^{2n})$ is a circle space, with Γ -fixed point set $\text{Fl}_\mathcal{D}(\mathbb{C}^n)$. Furthermore*

$$\kappa \left[\sigma_{\mathcal{D}I}^\mathbb{R} \right] = 2^{|\mathcal{I}|} \left[\sigma_I^\mathbb{C} \right],$$

where $[\sigma_I^\mathbb{C}] \in H^{2|\mathcal{I}|}(\text{Fl}_\mathcal{D}(\mathbb{C}^n))$.

Proof A representation theoretic computation involving the tangent bundles shows that the normal weights are all 2. By Theorem 4.2, it is enough to show that a) the Schubert cycles $[\sigma_{\mathcal{D}I}]$ form a basis of rational cohomology, b) for an appropriate complete real flag F_\bullet , $Z = \sigma_{\mathcal{D}I}^\mathbb{R}(F_\bullet)$ are good $\text{U}(1)$ -invariant cycles satisfying $\text{codim } Z = 2 \text{ codim } Z^\Gamma$, and c) have $\text{U}(1)$ -fixed point set $Z^\Gamma = \sigma_I^\mathbb{C}(F_\bullet^\mathbb{C})$. The $[\sigma_{\mathcal{D}I}^\mathbb{R}]$ form a basis by Theorem 3.12, so a) holds. It remains to choose a flag F_\bullet satisfying b) and c).

b) Let F_\bullet be a complete flag in \mathbb{R}^{2n} , such that F_{2i} are Γ -invariant, and let $F_\bullet^{\mathbb{C}}$ denote the corresponding complex flag $(F_0, F_2, \dots, F_{2n})$ in \mathbb{C}^n by the identification $\mathbb{R}^{2n} \leftrightarrow \mathbb{C}^n$. Then, $\sigma_{DI}^{\mathbb{R}}(F_\bullet)$ are halving cycles. Indeed, by the rank conditions (2.3), the complex points of $\sigma_{DI}^{\mathbb{R}}(F_\bullet)$ are the points of $\sigma_I^{\mathbb{C}}(F_\bullet^{\mathbb{C}})$ since

$$\dim_{\mathbb{R}}(W \cap W') = 2k \iff \dim_{\mathbb{C}}(W \cap W') = k$$

for any Γ -invariant subspaces $W, W' \subseteq \mathbb{R}^{2n}$. Therefore for this choice of F_\bullet , the $\sigma_{DI}^{\mathbb{R}}(F_\bullet)$ are Γ -invariant and $(\sigma_{DI}^{\mathbb{R}}(F_\bullet))^{\Gamma} = \sigma_I^{\mathbb{C}}(F_\bullet^{\mathbb{C}})$, so c) holds. A dimension count shows

$$\text{codim}_{\mathbb{R}} \sigma_{DI}^{\mathbb{R}}(F_\bullet) = 2 \text{codim}_{\mathbb{R}} \sigma_I^{\mathbb{C}}(F_\bullet^{\mathbb{C}})$$

and since $\Omega_I^{\mathbb{C}}$ is the unique top stratum of $\sigma_I^{\mathbb{C}}$, the $\sigma_{DI}^{\mathbb{R}}$ are good $U(1)$ -invariant cycles. □

We obtain the following Corollary:

Corollary 4.5 (Littlewood-Richardson coefficients) *In $H^*(\text{Fl}_{2D}; \mathbb{Q})$ the structure constants are given by*

$$[\sigma_{DI}^{\mathbb{R}}] \cdot [\sigma_{DJ}^{\mathbb{R}}] = \sum_K c_{IJ}^K [\sigma_{DK}^{\mathbb{R}}]$$

where c_{IJ}^K are the Littlewood-Richardson coefficients of the complex Schubert varieties:

$$[\sigma_I^{\mathbb{C}}] \cdot [\sigma_J^{\mathbb{C}}] = \sum_K c_{IJ}^K [\sigma_K^{\mathbb{C}}].$$

Proof By the Theorem and multiplicativity of κ ,

$$\begin{aligned} \kappa([\sigma_{DI}^{\mathbb{R}}] \cdot [\sigma_{DJ}^{\mathbb{R}}]) &= \kappa([\sigma_{DI}^{\mathbb{R}}]) \cdot \kappa([\sigma_{DJ}^{\mathbb{R}}]) = 2^{|I|+|J|} [\sigma_I^{\mathbb{C}}] \cdot [\sigma_J^{\mathbb{C}}] \\ &= 2^{|I|+|J|} \sum_K c_{IJ}^K [\sigma_K^{\mathbb{C}}]. \end{aligned}$$

Since $\kappa[\sigma_{DK}^{\mathbb{R}}] = 2^{|K|}[\sigma_K^{\mathbb{C}}]$ and $|K| = |I| + |J|$, the Corollary follows. □

The following corollaries follow analogously, using also the relation $\kappa p_j(S_i^{\mathbb{R}}) = 2^j c_j(S_i^{\mathbb{C}})$, where p_j, c_j denote Pontryagin and Chern classes respectively. For further details we refer to [41].

Corollary 4.6 (Giambelli formula type description) *In $H^*(\text{Fl}_{2D}; \mathbb{Q})$ the Schubert cycles can be expressed in terms of characteristic classes as follows:*

$$[\sigma_{DI}^{\mathbb{R}}] = q(p_*(S_i^{\mathbb{R}})) \iff [\sigma_I^{\mathbb{C}}] = q(c_*(S_i^{\mathbb{C}})),$$

that is the same polynomial $q \in \mathbb{Q}[x_i^j]$, $i = 1, \dots, m, j = 1, \dots, d_i$ describes the double real Schubert classes and complex Schubert classes in terms of Pontryagin classes $p_j(S_i^{\mathbb{R}})$ and Chern classes $c_j(S_i^{\mathbb{C}})$.

Corollary 4.7

$$\begin{aligned} H^* \left(\text{Fl}_{2D}^{\mathbb{R}} \right) &= \mathbb{Q} \left[p_* \left(S_i^{\mathbb{R}} \right) \right] / \mathcal{R} \left(p_* \left(S_i^{\mathbb{R}} \right) \right) \iff H^* \left(\text{Fl}_D^{\mathbb{C}} \right) \\ &= \mathbb{Q} \left[c_* \left(S_i^{\mathbb{C}} \right) \right] / \mathcal{R} \left(c_* \left(S_i^{\mathbb{C}} \right) \right), \end{aligned}$$

where $\mathcal{R}(x_*^j)$ denotes an ideal in the variables x_j^i , that is the same polynomial relations hold in the two cohomology rings in terms of Pontryagin and Chern classes of the respective tautological bundles.

5 Real Grassmannians

The Casian-Kodama conjecture [11] concerned the cohomology ring structure of real Grassmannians and was stated as follows. For $(K, N) = (2k, 2n), (2k + 1, 2n + 1)$ or $(2k, 2n + 1)$:

$$H^* \left(\text{Gr}_K \left(\mathbb{R}^N \right); \mathbb{Q} \right) \cong \mathbb{Q} \left[p_1, \dots, p_k, p'_1, \dots, p'_{n-k} \right] / \left(p_* \cdot p'_* - 1 \right) \quad (5.1)$$

where $p_i = p_i(S_1), p'_i = p_i(Q_1), p_* = \sum_{i=0}^k p_i, p'_* = \sum_{i=0}^{n-k} p'_i$ and

$$H^* \left(\text{Gr}_{2k+1} \left(\mathbb{R}^{2n} \right); \mathbb{Q} \right) \cong \mathbb{Q} \left[p_1, \dots, p_k, p'_1, \dots, p'_{n-k}, r \right] / \left(p_* \cdot p'_* - 1, r^2 \right) \quad (5.2)$$

where r is the Schubert class corresponding to the L -shape Young diagram: $(n - k, 1^{k-1})$. The conjecture of Casian and Kodama (5.1) and (5.2) on the cohomology ring was completely settled even equivariantly using different methods by Takeuchi, He, Sadykov and Carlson [10,30,47,50], see Q3) in Sect. 1.4.

Another kind of description of the ring structure is obtained by giving an additive basis in Schubert cycles and by determining their structure constants. These results are due to Pontryagin, Fuchs, Finashin and Kharlamov [23,44] and [20]. We briefly summarize how to obtain these results from the previous computations.

5.1 Additive structure

A convenient way to parametrize the Schubert varieties in Grassmannians is by Young diagrams $\lambda \subseteq K \times (N - K)$. One has the following conversion formulas between $\lambda \subseteq K \times (N - K)$ and $I \in \binom{N}{K}$:

$$\lambda_j = N - K + j - I_j, \quad I_j = N - K + j - \lambda_j. \quad (5.3)$$

Fig. 4 The L -operation on $\lambda = (3, 1, 0) \subseteq 3 \times 4$

for $j = 1, \dots, K$. Before stating the Schubert cycle description of $H^*(\text{Gr}_K(\mathbb{R}^N); \mathbb{Q})$ it is convenient to introduce the L -operation on Young diagrams: given $\lambda \subseteq K \times (N - K)$, let $L\lambda \subseteq (K + 1) \times (N - K + 1)$ be the partition

$$L\lambda := (N - K + 1, \lambda_1 + 1, \lambda_2 + 1, \dots, \lambda_K + 1).$$

In terms of Young diagrams, the diagram contains the first row and column, and the complement of this L-shape is the Young diagram λ , see Fig. 4 (the added L-shape is marked with bullet points). We call the corresponding Schubert varieties $\sigma_{L\lambda}$ L -Schubert varieties. Recall that $D\lambda \subseteq 2k \times 2(n - k)$ denotes the double of a Young diagram $\lambda \subseteq k \times (n - k)$ defined earlier (Fig. 2).

Theorem 5.1

$$H^*(\text{Gr}_K(\mathbb{R}^N); \mathbb{Q}) = \begin{cases} \mathbb{Q} \langle [\sigma_{D\lambda}], [\sigma_{L(D\lambda)}] : \lambda \subseteq k \times (n - k) \rangle & \text{if } N \text{ is even and } K \text{ is odd} \\ \mathbb{Q} \langle [\sigma_{D\lambda}] : \lambda \subseteq k \times (n - k) \rangle & \text{else.} \end{cases}$$

where $k = \lfloor K/2 \rfloor, n = \lfloor N/2 \rfloor$.

Proof In terms of Young diagrams, the incidence coefficients (3.6) are the following (see also [11]). If μ is a partition obtained from λ by increasing λ_j by 1, then

$$[\sigma_\lambda, \sigma_\mu] = \begin{cases} 0 & \lambda_j - j \text{ odd} \\ \pm 2 & \lambda_j - j \text{ even} \end{cases} \tag{5.4}$$

Then σ_λ is a cycle if and only if for all partitions μ obtained by increasing λ_j by 1, $\lambda_j - j$ is odd. This implies that double Schubert varieties $\sigma_{D\lambda}$ and double L -Schubert varieties $\sigma_{L(D\lambda)}$ are cycles – possibly torsion. However, $[\sigma_{D\lambda}, \sigma_\mu] = 0$ for all $\dim \sigma_\mu = \dim \sigma_{D\lambda} + 1$, so the $[\sigma_{D\lambda}]$ do not appear in any relations and therefore are linearly independent. A similar computation shows that if K odd and N even, $[\sigma_{L(D\lambda)}]$ appear with zero coefficient in every incidence relation, so these classes are linearly independent. By counting ranks, (5.1) and (5.2) imply that

$$\dim_{\mathbb{Q}} H^*(\text{Gr}_K(\mathbb{R}^N); \mathbb{Q}) = \begin{cases} 2 \binom{n}{k} & N \text{ even } K \text{ odd} \\ \binom{n}{k} & \text{else.} \end{cases}$$

which implies that these Schubert classes form a basis. □

5.2 Multiplicative structure

The $\text{Gr}_K(\mathbb{R}^N)$ are circle spaces unless K is odd and N is even. If K and N is even, this is a special case of Theorem 4.4. In particular, the Giambelli and Pieri formulas

hold by replacing all $[\sigma_\lambda^{\mathbb{C}}]$ with $[\sigma_{D\lambda}^{\mathbb{R}}]$ in the formulas. The remaining cases: K odd N even and K even N odd are both nonorientable. We now proceed to show that they are also circle spaces.

Proposition 5.2 *The natural inclusions induce isomorphisms of cohomology with rational coefficients*

$$H^* \left(\text{Gr}_{2k} \left(\mathbb{R}^{2n} \right) \right) \cong H^* \left(\text{Gr}_{2k} \left(\mathbb{R}^{2n+1} \right) \right) \cong H^* \left(\text{Gr}_{2k+1} \left(\mathbb{R}^{2n+1} \right) \right)$$

and the descriptions given in Corollaries 4.5, 4.6, 4.7 hold for $\text{Gr}_{2k}(\mathbb{R}^{2n+1})$ and $\text{Gr}_{2k+1}(\mathbb{R}^{2n+1})$ as well.

Proof Let $F_\bullet^{\mathbb{R}} \in \text{Fl}(\mathbb{R}^{2n+1})$ be the standard complete flag. Identify $\mathbb{R}^{2n+1} = \mathbb{R} \oplus \mathbb{C}^n$ as $\Gamma = \text{U}(1)$ -representations; let the trivial representation be the first coordinate $\mathbb{R} = \langle e_1 \rangle$. This induces actions on $\text{Gr}_{2k+1}(\mathbb{R}^{2n+1})$ and $\text{Gr}_{2k}(\mathbb{R}^{2n+1})$, whose fixed point set can be identified with $\text{Gr}_k(\mathbb{C}^n)$. By the definition of the $\text{U}(1)$ -action, $F_\bullet^{\mathbb{C}} = (\langle e_2, e_3 \rangle, \langle e_2, e_3, e_4, e_5 \rangle, \dots, \langle e_2, \dots, e_{2n+1} \rangle)$ is a complete complex flag $F_\bullet^{\mathbb{C}} \in \text{Fl}(\mathbb{C}^n)$. The rank description (2.3) implies that double Schubert varieties $\sigma_{D\lambda}(F_\bullet^{\mathbb{R}})$ are halving cycles, with fixed point set $\sigma_\lambda^{\mathbb{C}}(F_\bullet^{\mathbb{C}})$.

We will apply Theorem 4.2, but since $\text{Gr}_K(\mathbb{R}^{2n+1})$ are not orientable, we have to verify the conditions described in Remark 4.3. By He’s Theorem A.3, any flag manifold is a Poincaré duality space, and $\text{fd}(X) = 4k(n - k)$ and $\text{fd}(X^\Gamma) = 2k(n - k)$. So the conditions of Remark 4.3 are satisfied and one can apply Theorem 4.2 to conclude.

Finally, the natural inclusions induce the isomorphisms. Indeed, the characteristic classes are mapped into each other via the natural inclusions, so there is a system of generators mapped into a system of generators with the same relations. For example,

$$i : \text{Gr}_{2k}(\mathbb{R}^{2n}) \hookrightarrow \text{Gr}_{2k}(\mathbb{R}^{2n+1})$$

pulls back $i^* p_j(S^{2n+1}) = p_j(S^{2n})$ and $i^* p_j(Q^{2n+1}) = p_j(Q^{2n})$ (even though the pullback $i^* Q^{2n+1} = Q^{2n} \oplus \varepsilon$). □

Proposition 5.3 *The structure constants of $[\sigma_{D\lambda}]$ and $[\sigma_{L(D\lambda)}]$ in $H^*(\text{Gr}_{2k+1}(\mathbb{R}^{2n}))$ are completely determined by the Littlewood-Richardson structure constants of $[\sigma_{D\lambda}]$ (Corollary 4.5) and*

$$[\sigma_{D\lambda}] \cdot [\sigma_{L0}] = [\sigma_{L(D\lambda)}], \quad [\sigma_{L0}]^2 = 0.$$

Proof Since $[\sigma_{L0}] \in H^{2n-1}$ lives in odd degree, and multiplication is graded commutative, $[\sigma_{L0}]^2$ is 2-torsion, therefore zero rationally.

To show $[\sigma_{D\lambda}] \cdot [\sigma_{L0}] = [\sigma_{L(D\lambda)}]$, we use the following lemma. □

Lemma 5.4 *In $\text{Gr}_k(\mathbb{R}^n)$, there exist transverse flags E_\bullet, F_\bullet and a flag G_\bullet , such that*

$$\sigma_{L0}(E_\bullet) \cap \sigma_\lambda(F_\bullet) = \sigma_{L\lambda}(G_\bullet) \tag{5.5}$$

Proof Let E_\bullet be the standard flag, F_\bullet the opposite flag

$$F_\bullet = \langle e_n \rangle \subseteq \langle e_n, e_{n-1} \rangle \subseteq \dots \subseteq \langle e_n, e_{n-1}, \dots, e_2 \rangle \subseteq \langle e_n, e_{n-1}, \dots, e_1 \rangle$$

and G_\bullet be obtained from F_\bullet by exchanging e_1 and e_n :

$$G_\bullet = \langle e_1 \rangle \subseteq \langle e_1, e_{n-1} \rangle \subseteq \dots \subseteq \langle e_1, e_{n-1}, \dots, e_2 \rangle \subseteq \langle e_1, e_{n-1}, \dots, e_3, e_2, e_n \rangle.$$

E_\bullet and F_\bullet are transverse flags, which imply that the Schubert varieties $\sigma_{L0}(E_\bullet) \cap \sigma_\lambda(F_\bullet)$ intersect transversely. The rank conditions defining $\sigma_{L0}(E_\bullet)$ translate to

$$U \in \sigma_{L0} \iff E_1 \subseteq U \subseteq E_{n-1}$$

in particular, $\sigma_{L0}(E_\bullet)$ is a subGrassmannian $\text{Gr}_k(\mathbb{R}^{n-2})$. The following observation allows us to conclude: if $E_1 \subseteq U \subseteq E_{n-1}$, then

$$\dim(U \cap F_j) = k \iff \dim(U \cap G_j) = k + 1$$

By comparing the rank conditions defining σ_λ and $\sigma_{L\lambda}$ the two sides of (5.5) are equal. □

- Remark 5.5** (i) The previous lemma was stated for arbitrary k and n ; a simple verification shows that the subGrassmannian σ_{L0} is always coorientable and therefore a cycle. However, the computation which shows that it appears in every incidence relation with zero coefficient only holds if k is odd and n is even, otherwise $[\sigma_{L0}]$ is a 2-torsion element.
- (ii) If one defines the usual $U(1)$ -action on \mathbb{R}^{2n} by identifying it with \mathbb{C}^n , the induced action on $\text{Gr}_{2k+1}(\mathbb{R}^{2n})$ has no fixed points; indeed, \mathbb{C}^n has no real odd dimensional invariant subspaces. $\text{Gr}_{2k+1}(\mathbb{R}^{2n})$ has zero Euler characteristic so it cannot be a circle space.

6 Integer coefficients and Steenrod squares

It is a classical result that all torsion in $H^*(\text{Gr}_k(\mathbb{R}^\infty); \mathbb{Z})$ is of order 2, see e.g. [6, Theorem 24.7]. By a theorem of Ehresmann [16, p. 81], this also holds in the case of finite Grassmannians. Therefore the rational and mod 2 reductions of an integer cohomology class completely determine its value. In particular, one can express the integer classes of Schubert cycles in terms of Pontryagin classes and Bockstein’s of Stiefel-Whitney classes, see Theorem 6.7 below. In this chapter, we extend Ehresmann’s theorem to the case of even real flag manifolds $\text{Fl}_{2\mathcal{D}}$, and conjecture that it holds in general:

Theorem 6.1 *For even real flag manifolds $2 \text{Tor}(H^*(\text{Fl}_{2\mathcal{D}}; \mathbb{Z})) = 0$, i.e. every torsion element of $H^*(\text{Fl}_{2\mathcal{D}}; \mathbb{Z})$ is of order 2. In particular, if β denotes the Bockstein*

homomorphism and H_{free}^* denotes the free part:

$$H^*(\text{Fl}_{2\mathcal{D}}; \mathbb{Z}) = H_{\text{free}}^*(\text{Fl}_{2\mathcal{D}}; \mathbb{Z}) \bigoplus \text{Im } \beta$$

After some preparation in Sect. 6.3, we prove this Theorem in Sect. 6.3.3 using Proposition 6.9 of Borel and Hirzerbruch which requires computing the Poincaré polynomial of Bockstein cohomology P_β .

For a general space X , one way to compute $H^*(X; \mathbb{Z})$ is by computing the mod p Bockstein spectral sequences. Degeneration of the mod 2 Bockstein spectral sequence on the E_2 -page is equivalent to saying that the 2-primary part of $H^*(X; \mathbb{Z})$ consists entirely of elements of order 2. The differential d_1 on the first page $E_1^{p,q} = H^{p+q}(X; \mathbb{F}_2)$ of the mod 2 Bockstein spectral sequence is the first Steenrod square Sq^1 . In order to compute the E_2 -page, we will give a combinatorial description of the Sq^1 -action on the additive basis of Schubert cycles, which is strongly related to the incidence coefficients computed earlier, see Proposition 6.3. We will then use this description to compute the E_2 -page of the Bockstein spectral sequence.

The cohomology groups $H^*(\text{Fl}_{2\mathcal{D}}; \mathbb{Z})$ then can be completely determined by using this theorem, the Cartan description of Section A and the universal coefficient theorem. This is a combinatorial computation which can be carried out similarly as was done in [31] for the case of Grassmannians. It relies on the following observation: if all torsion in $H^*(X; \mathbb{Z})$ is of order two, then $P_{\text{Tor}} = \frac{t}{t+1}(P_2 - P_0)$, where P_{Tor} denotes the Poincaré polynomial of the ranks of \mathbb{Z}_2 's in $H^*(X; \mathbb{Z})$, P_2 and P_0 denote the mod 2 and rational coefficient Poincaré polynomials of X .

Proposition 6.2 *Let $\mathcal{D} = (d_1, \dots, d_r)$, $N = \sum d_i$. The Poincaré polynomial of the ranks of \mathbb{Z}_2 's in $H^*(\text{Fl}_{2\mathcal{D}}^{\mathbb{R}}; \mathbb{Z})$ is given by*

$$P_{\text{Tor}}(\text{Fl}_{2\mathcal{D}}) = \frac{t}{t+1} \left(\frac{\prod_{j=1}^{2N} (1-t^j)}{\prod_{i=1}^r \prod_{j=1}^{2d_i} (1-t^j)} - \frac{\prod_{j=1}^N (1-t^{4j})}{\prod_{i=1}^r \prod_{j=1}^{d_i} (1-t^{4j})} \right).$$

Proof The Poincaré polynomial P_2 of mod 2 cohomology is a classical result of Borel [5] and rational coefficient Poincaré polynomial P_0 follows from the He's Theorem A.3, [32]. □

6.1 Steenrod squares

Lenart [40] computed the *Steenrod coefficients* $c_{\lambda\mu}^k \in \mathbb{F}_2$ in complex Grassmannians:

$$\text{Sq}^k[\sigma_\lambda] = \sum_{\mu} c_{\lambda\mu}^k [\sigma_\mu]$$

As he remarks, the Steenrod coefficients are obstructions for the triviality of the attaching maps: if $c_{\lambda\mu}^k$ is nonzero, then the corresponding attaching map is nontrivial. He also gives an example [40, Section 6], where the converse does not hold. The more

general case of Steenrod coefficients c_{IJ}^k for arbitrary flag manifolds of simply connected, semisimple Lie groups (and arbitrary p) was determined by Duan and Zhao [14]. Notice that the distinction of real and complex is irrelevant; by results of [22] and [54]:

$$\text{Sq}^{2k} [\sigma_I^{\mathbb{C}}] = \sum_J c_{IJ}^k [\sigma_J^{\mathbb{C}}] \iff \text{Sq}^k [\sigma_I^{\mathbb{R}}] = \sum_J c_{IJ}^k [\sigma_J^{\mathbb{R}}].$$

On the other hand, for $k = 1$, the Steenrod coefficients c_{IJ}^1 for real flag manifolds vanish if and only if the incidence coefficients $[\Omega_I, \Omega_J]$ vanish:

Proposition 6.3 *For all $I, J \in \text{OSP}(\mathcal{D})$, set $c_{IJ} := |[\Omega_I, \Omega_J]/2| \in \mathbb{F}_2$ where $[\Omega_I, \Omega_J]$ are the incidence coefficients, described in (3.6). Then*

$$\text{Sq}^1 [\sigma_I] = \sum c_{IJ} [\sigma_J].$$

For a related statement for the case of Grassmannians in the algebraic geometric context (Chow-Witt ring) see [57, Theorem 1.1]. The Proposition follows from the following classical viewpoint on Bockstein homomorphisms (see e.g. [42]):

Lemma 6.4 *If (C, d) is a cochain complex, then the Bockstein homomorphism of $(C, 2d)$*

$$\beta : H^*(C \otimes \mathbb{F}_2, 2d \otimes \mathbb{F}_2 = 0) \rightarrow H^{*+1}(C, 2d)$$

satisfies

$$\beta[\rho z] = [dz] \in H^{*+1}(C, 2d),$$

for all $z \in C$, where $\rho : C \rightarrow C \otimes \mathbb{F}_2$ is the mod 2 reduction.

The proof is an unraveling of the definition of the Bockstein homomorphism.

Proof (Proof of Proposition) Apply the Lemma to the Vassiliev complex (all coefficients are ± 2) and use the classical fact that the mod 2 reduction of the Bockstein homomorphism is Sq^1 . □

Thus the knowledge of the incidence coefficients (3.6) yields a combinatorial formula for the Steenrod coefficients of Sq^1 in an arbitrary partial flag manifold in terms of Schubert cycles.

Remark 6.5 There is a geometric proof of Proposition 6.3. This involves the Thom-Wu theorem which states that if $i : Z \hookrightarrow X$ is a smooth submanifold, then $\text{Sq}^k[Z] = i_! w_k(\nu_i)$. Together with the description of $[\Omega_I, \Omega_J]$ in Proposition 3.1, this proves Proposition 6.3.

6.2 Integral cycles

Before proving Theorem 6.1, we deduce some easy consequences about integral cycles.

Proposition 6.6 *Let X be a manifold satisfying $2 \operatorname{Tor}(H^*(X; \mathbb{Z})) = 0$. Then every integral cycle $[Z] \in H^*(X; \mathbb{Z})$ is one of the two following types*

- $[Z] \in \operatorname{Im} \beta$, in which case $2[Z] = 0$ or
- $[Z \bmod 2] \neq 0 \in \ker \operatorname{Sq}^1 / \operatorname{Im} \operatorname{Sq}^1$, in which case $[Z] \neq 0$ rationally.

In particular, by Lemma 6.4, the 2-torsion part of $H^*(\operatorname{Fl}_{2\mathcal{D}}; \mathbb{Z})$ is generated by cycles of the form $[d\Omega_I/2]$.

We relate Schubert cycles to integral characteristic classes. Denote a Stiefel-Whitney monomial in $H^*(\operatorname{Fl}_{\mathcal{D}}(\mathbb{R}^N); \mathbb{F}_2)$ by

$$w_M = \prod_{i,j} w_i(D_j)^{m_{ij}},$$

where $M = (m_{ij}) \in \mathbb{N}^N$ denotes a multiindex ($N = \sum_{i=1}^r d_i$). Then every element of $H^*(\operatorname{Fl}_{\mathcal{D}}(\mathbb{R}^N); \mathbb{F}_2)$ can be written as a sum of w_M 's (not necessarily uniquely!), write $\sum w_M$ for a generic element. Then $\sum w_M$ is the mod 2 reduction of a 2-torsion class in $H^*(\operatorname{Fl}_{\mathcal{D}}; \mathbb{Z})$ iff $\sum w_M \in \operatorname{Im} \operatorname{Sq}^1$. For such elements, denote by $\sum v_M$ the unique second order element in $\operatorname{Im} \beta \subseteq H^*(\operatorname{Fl}_{2\mathcal{D}}; \mathbb{Z})$ whose mod 2 reduction equals $\sum w_M$.

A consequence of Theorem 6.1 is that from the mod 2 and rational descriptions of double Schubert classes $[\sigma_{DI}]$, one can express the integer classes $[\sigma_{DI}]$ in terms of characteristic classes. Using the previous notations, we can give a formula:

Theorem 6.7 *The integral classes $[\sigma_{DI}] \in H^*(\operatorname{Fl}_{2\mathcal{D}}(\mathbb{R}^N); \mathbb{Z})$ equal*

$$[\sigma_{DI}] = s_I(p_i(D_j)) + \left\{ s_{DI}(v_{i,j}) - s_I(v_{i,2j}^2) \right\},$$

$j = 1, \dots, r$ and $i = 1, \dots, d_j$ where $s_I(x_{i,j})$ denotes the Schubert polynomial in the variables $x_{i,j}$ (in terms of elementary symmetric polynomials [3, Sect. 5]).

Here $s_{DI}(w_i(D_j)) - s_I(w_{2i}(D_j)^2) \in H^*(\operatorname{Fl}_{2\mathcal{D}}; \mathbb{F}_2)$ is in $\operatorname{Im} \operatorname{Sq}^1$, and therefore lifts to a unique second order element denoted $\{s_{DI}(v_{i,j}) - s_I(v_{i,2j}^2)\} \in H^*(\operatorname{Fl}_{2\mathcal{D}}; \mathbb{Z})$.

Proof The rational class is $[\sigma_{DI}] = s_I(p_{i,j})$ by the generalized Borel-Haefliger theorem (Corollary 4.6) and the mod 2 class is $s_{DI}(w_{i,j})$ by the classical mod 2 Borel-Haefliger theorem. The theorem then follows from the fact that the mod 2 reduction of the j th integral Pontryagin class p_j is w_{2j}^2 . □

Remark 6.8 Contrary to what the notation might suggest, $\{s_{DI}(v_{i,j}) - s_I(v_{i,2j}^2)\}$ is not a polynomial in some classes $v_{i,j}$; it is an element, whose mod 2 reduction is the polynomial $s_{DI}(w_{i,j}) - s_I(w_{i,2j}^2)$. Determining the class $[\sigma_{DI}]$ in terms of multiplicative generators of $H^*(\operatorname{Fl}_{2\mathcal{D}}; \mathbb{Z})$ is a challenge we will not consider.

6.3 Proof of Theorem 6.1

In the rest of this section we prove Theorem 6.1, but first we recall some generalities about the Bockstein spectral sequence and the Bockstein cohomology of a space.

6.3.1 Bockstein cohomology

The *Bockstein cohomology* of a topological space X can be defined as follows: since $Sq^1 : H^*(X; \mathbb{F}_2) \rightarrow H^{*+1}(X; \mathbb{F}_2)$ satisfies $Sq^1 \circ Sq^1 = 0$, one can regard $H^*(X; \mathbb{F}_2)$ as a chain complex and compute its cohomology

$$H_\beta^*(X) := H^* \left(H^*(X; \mathbb{F}_2); Sq^1 \right).$$

Since Sq^1 is the differential d_1 on the page $E_1^{p,q} = H^{p+q}(X; \mathbb{F}_2)$ of the mod 2 Bockstein spectral sequence, so $H_\beta^*(X)$ is just the E_2 -page of the Bockstein spectral sequence. Denote by $P_\beta(X)$ the Poincaré polynomial of $H_\beta^*(X)$ and by $P_0(X)$ the Poincaré polynomial of $H^*(X; \mathbb{Q})$. We will use the following Proposition of Borel-Hirzebruch, [4] Lemma 30.4 and 30.5 (1), cf. also [6]:

Proposition 6.9 *If $H^*(X; \mathbb{Z})$ is finitely generated, then the 2-primary component of $H^*(X; \mathbb{Z})$ consists of elements of order 2 (i.e. the Bockstein spectral sequence degenerates) if and only if*

$$P_\beta(X) = P_0(X).$$

Borel and Hirzebruch show in [4, 30.5] that in the case of infinite Grassmannians $G_N = Gr_N(\mathbb{R}^\infty)$

$$P_0(G_N) = P_\beta(G_N) = \prod_{i=1}^{\lfloor \frac{N}{2} \rfloor} \frac{1}{1 - t^{4i}}. \quad (6.1)$$

In order to compute P_β , $\mathbb{F}_2[w_1, \dots, w_N]$ is decomposed into the tensor product of subalgebras A_i each invariant under Sq^1 . The Poincaré polynomial P_β is then the product of the Poincaré polynomials of A_i : $P_\beta = \prod_i P_{A_i}$. The generators of H_β^* are also identified to be $[w_{2i}^2]$.

We will reduce the finite case to the infinite case, so let us discuss the infinite version of flag manifolds. Given $\mathcal{D} = (d_1, \dots, d_r)$, let

$$\mathcal{D}^m = (d_1, \dots, d_{r-1}, d_r + m), \quad (6.2)$$

m possibly infinite. Note that $Fl_{\mathcal{D}^\infty}$ is the classifying space of the parabolic subgroup $P = GL(d_1, \dots, d_{r-1})$ (using the notation of Sect. 2.2).

Proposition 6.10

$$P_\beta(\text{Fl}_{2\mathcal{D}^\infty}) = \prod_{i=1}^{r-1} \prod_{j=1}^{d_i} \frac{1}{1-t^{4j}} = P_0(\text{Fl}_{2\mathcal{D}^\infty})$$

and $H_\beta^*(\text{Fl}_{2\mathcal{D}^\infty})$ is generated by $[w_{2j}^2(D_i)]$. In particular, all torsion of $H^*(\text{Fl}_{2\mathcal{D}^\infty}; \mathbb{Z})$ is of order 2.

Proof Using that

$$H^*(\text{Fl}_{2\mathcal{D}^\infty}) = \mathbb{F}_2[w_j(D_i) : i = 1, \dots, r-1, j = 1, \dots, d_i],$$

this follows from (6.1), similarly to Borel’s computations [6, pp. 85–86]. □

In the finite case, matters are complicated by the relations, since such a decomposition into subalgebras does not exist. This is why we will use the additive (Schubert basis) description of the cohomology groups, together with the combinatorial description of Sq^1 (Proposition 6.3).

6.3.2 Stabilization of Schubert classes

Next we discuss stabilization of Schubert classes. With the notation \mathcal{D}^m introduced in (6.2), we have direct sum maps (see Sect. 2.2.3):

$$\mathcal{K}_m : \text{Fl}_{\mathcal{D}}(\mathbb{R}^N) \hookrightarrow \text{Fl}_{\mathcal{D}^m}(\mathbb{R}^{N+m}).$$

The current indexing of the Schubert cycles does not satisfy nice stability properties, so from now on we will change the convention of indexing the Schubert varieties σ_I , $I \in \text{OSP}(\mathcal{D})$. Let $\vee : \text{OSP}(\mathcal{D}) \rightarrow \text{OSP}(\mathcal{D})$ be the involution defined as follows: for $I \in \text{OSP}(\mathcal{D})$, replace each element $k \in I_j$ by $N + 1 - k$:

$$I_j^\vee := \{N + 1 - k : k \in I_j\}$$

for all j , where $|\mathcal{D}| = N$. Let $\sigma_I := \sigma_{I^\vee}$ and $\Omega_I := \Omega_{I^\vee}$ for all $I \in \text{OSP}(\mathcal{D})$. For complete flag manifolds $\mathcal{D} = (1^N)$, this indexing convention agrees with [24], see also [26, p. 20]. With the new conventions $\ell(I) = \text{codim } \sigma_I$ (for the notation $\ell(I)$ see (2.4)) and Ω_I and Ω_J are adjacent if J is obtained from I by exchanging $a \in I_\alpha$ with some $b \in I_\beta$, $a < b$, $\alpha < \beta$. The incidence relations are (for the notation $T_I(a, b)$ see (3.5)):

$$[\Omega_I, \Omega_J] = \begin{cases} 0, & T_I(a, b) \text{ even} \\ \pm 2, & T_I(a, b) \text{ odd} \end{cases} \tag{6.3}$$

With this indexing convention, Schubert classes mod 2 satisfy the following stabilization property (this can be shown by a transversality argument):

$$\mathcal{K}_m^* [\sigma_J] = \begin{cases} [\sigma_I] & \text{if } J = I^m \\ 0 & \text{else,} \end{cases} \tag{6.4}$$

where for $I \in \text{OSP}(\mathcal{D})$, define

$$I^m := (I_1, I_2, \dots, I_{r-1}, I_r \cup \{N + 1, \dots, N + m\}).$$

In particular,

$$\ker \mathcal{K}_m^* = \langle [\sigma_I] : \exists k > N : k \notin I_r \rangle. \tag{6.5}$$

Remark 6.11 For $I \in \text{OSP}(\mathcal{D})$, stabilization implies that there exists $s_I \in H^*(\text{Fl}_{\mathcal{D}^\infty}; \mathbb{F}_2)$, such that $\mathcal{K}_\infty^* s_I = [\sigma_I]$ and factors through $[\sigma_{I^m}]$ for all m . Since $\text{Fl}_{\mathcal{D}^\infty}$ is the classifying space of $\text{GL}(d_1, \dots, d_{r-1})$, $s_I \in H^*(\text{Fl}_{\mathcal{D}^\infty})$ is a polynomial $q(w_i^j)$ in the universal Stiefel-Whitney classes w_i^j , and since $\mathcal{K}_\infty^* w_i^j = w_i(D_j)$, stabilization provides universal formulas $[\sigma_{I^m}] = q(w_i(D_j))$ in terms of characteristic classes (the minimal Schubert polynomials, see [3, Sect. 5]).

Stabilization also implies that there exists a universal formula for Steenrod squares in terms of Schubert cycles: there exist $c_{IJ}^k \in \mathbb{F}_2$, such that

$$\text{Sq}^k s_I = \sum c_{IJ}^k s_J, \quad \text{Sq}^k [\sigma_{I^m}] = \sum c_{IJ}^k [\sigma_{J^m}]$$

holds for all m . Indeed, there are only finitely many s_I in $H^*(\text{Fl}_{\mathcal{D}^\infty}; \mathbb{F}_2)$ of fixed codimension, and Steenrod operations are natural.

6.3.3 Bockstein cohomology of even flag manifolds

Now we start computing Bockstein cohomology using Proposition 6.3. Let

$$Z_m := \ker \left(\text{Sq}^1 : H^*(\text{Fl}_{\mathcal{D}^m}) \rightarrow H^{*+1} \right), \quad B_m := \text{Im} \left(\text{Sq}^1 : H^{*-1}(\text{Fl}_{\mathcal{D}^m}) \rightarrow H^* \right),$$

both graded \mathbb{F}_2 -vector spaces, let $H_m := Z_m/B_m$, $q_m : Z_m \rightarrow H_m$ and denote $Z := Z_0$ and $B := B_0$, $H := H_0$, $q := q_0$. In the following we compare Z_m with Z and B_m with B using the description (6.5). Naturality of Sq^1 implies that

- (i) $B = \mathcal{K}_m^* B_m$,
- (ii) $Z \supseteq \mathcal{K}_m^* Z_m$.

These imply that $q \circ \mathcal{K}_m^* : Z_m \rightarrow Z \rightarrow H$ induces a map $\hat{\mathcal{K}}_m^* : H_m \rightarrow H$ satisfying

$$\ker \hat{\mathcal{K}}_m^* = q_m (\ker \mathcal{K}_m^*). \tag{6.6}$$

Lemma 6.12 *Let $\mathcal{D} = (2d_1, \dots, 2d_r)$. For even flag manifolds $\text{Fl}_{\mathcal{D}}$: If $[\sigma_I] \in Z$, then $[\sigma_I] \in \mathcal{K}_1^* Z_1$.*

Proof Assume $[\sigma_I] \in Z$ for some $I \in \text{OSP}(\mathcal{D})$. Write

$$\text{Sq}^1[\sigma_{I^1}] = \sum_{J \in T} [\sigma_J] \in H^*(\text{Fl}_{\mathcal{D}^1}),$$

where by assumption $[\sigma_J] \in \ker \mathcal{K}_1^*$ for all $J \in T \subseteq \text{OSP}(\mathcal{D}^1)$. If $[\sigma_J] \in \ker \mathcal{K}_1^*$, then by (6.5) J is obtained from I^1 by exchanging $N + 1 \in I_r^1$ with some $a \in I_\alpha^1$ which satisfies

$$a = \max I_\alpha^1 > \max I_{\alpha+1}^1 > \dots > \max I_{r-1}^1, \tag{6.7}$$

otherwise the number of inversions changes by at least 2. To determine $[\Omega_I, \Omega_J]$, we use (6.3), recall the notations of (3.5). Clearly, $G_{I^1}(N + 1, \alpha - 1, r - 1) = 0$. By (6.7),

$$L_{I^1}(a, \alpha, r) = \sum_{i=\alpha+1}^{r-1} 2d_i$$

so by (6.3), $[\Omega_I, \Omega_J] = 0$. Hence the Steenrod coefficients also vanish by Proposition 6.3, therefore T is empty, proving the lemma. □

Corollary 6.13 *For even flag manifolds $\text{Fl}_{2\mathcal{D}}$:*

$$Z = \mathcal{K}_\infty^* Z_\infty, \quad H = \hat{\mathcal{K}}_\infty^* H_\infty,$$

Proof Let $I \in \text{OSP}(\mathcal{D})$ and $J \in \text{OSP}(\mathcal{D}^m)$. A simple computation involving the number of inversions shows that I^m and J are adjacent in $\text{Fl}_{\mathcal{D}^m}$ iff $J = K^{m-1}$ for some $K \in \text{OSP}(\mathcal{D}^1)$ and I^1 and K are adjacent in $\text{Fl}_{\mathcal{D}^1}$. Therefore $[\sigma_{I^1}] \in Z_1$ iff $[\sigma_{I^m}] \in Z_m$, so $Z = \mathcal{K}_1^* Z_1 = \mathcal{K}_m^* Z_m$ for all m . This also implies surjectivity of $\hat{\mathcal{K}}_\infty^*$. □

Now we can finally prove Theorem 6.1:

Proof of Theorem 6.1 It follows from results of Borel’s thesis that $\text{Tor}(H^*(\text{Fl}_{\mathcal{D}}; \mathbb{Z}))$ is 2-primary (see [5, Propositions 29.1, 30.1]), so we can concentrate on $p = 2$. By Corollary 6.13:

$$P_\beta(\text{Fl}_{2\mathcal{D}}) = P_\beta(\text{Fl}_{2\mathcal{D}^\infty}) - P(\ker \hat{\mathcal{K}}_m^*)$$

Let $Q \subseteq Z_m$ be a subspace such that $q : Q \xrightarrow{\cong} H_m$. Then the Poincaré polynomials satisfy

$$P(\ker \hat{\mathcal{K}}_m^*) = P(Q \cap \ker \mathcal{K}_m^*).$$

By Proposition 6.10, such a subspace is given by $Q = \mathbb{F}_2[w_{2j}(D_i)^2]$, so by (6.4)

$$Q \cap \ker \mathcal{K}_\infty^* = \langle s_J(w_{2j}^2) : J \neq I^\infty, I \in \text{OSP}(2\mathcal{D}) \rangle. \tag{6.8}$$

Denote the rational coefficient pullback induced by \mathcal{K}_∞ by

$$\mathcal{K}_0^* : H^*(\text{Fl}_{2\mathcal{D}^\infty}; \mathbb{Q}) \rightarrow H^*(\text{Fl}_{2\mathcal{D}}; \mathbb{Q})$$

Since \mathcal{K}_0^* is also surjective,

$$P_0(\text{Fl}_{2\mathcal{D}}) = P_0(\text{Fl}_{2\mathcal{D}^\infty}) - P(\ker \mathcal{K}_0^*)$$

and

$$\ker \mathcal{K}_0^* = \langle s_J(p_j) : J \neq I^\infty, I \in \text{OSP}(2\mathcal{D}) \rangle. \tag{6.9}$$

Comparing (6.8) and (6.9), $P(\ker \mathcal{K}_0^*) = P(\ker \hat{\mathcal{K}}_m^*)$, and since $P_0(\text{Fl}_{2\mathcal{D}^\infty}) = P_\beta(\text{Fl}_{2\mathcal{D}^\infty})$ by Proposition 6.10, $P_0(\text{Fl}_{2\mathcal{D}}) = P_\beta(\text{Fl}_{2\mathcal{D}})$ and we can conclude by Proposition 6.9. \square

Remark 6.14 In the case of Grassmannians $\text{Gr}_K(\mathbb{R}^N)$, the previous proof can also be adapted, and one can show that $P_\beta = P_0$. Lemma 6.12 also holds, except when K is odd and N even, when $Z \setminus Z_1$ also contains the L -Schubert classes. In the case of arbitrary flag manifolds $\text{Fl}_{\mathcal{D}}$ these computations appear to be more complicated; it is no longer true that the Bockstein cohomology generators are Schubert varieties $[\sigma_I]$, but sums of them, see Appendix B.

Conjecture 6.15 For any real flag manifold (more generally any R -space) all torsion of $H^*(\text{Fl}_{\mathcal{D}}; \mathbb{Z})$ is of order 2.

Remark 6.16 If this conjecture holds, then the cohomology groups $H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Z})$ can be determined from the Universal Coefficient Theorem as in [31], see also Proposition 6.2.

7 Enumerative applications: lower bounds

The cohomology ring structure in terms of Schubert classes gives information about enumerative geometric *Schubert problems*:

Given generic complete flags $F_\bullet^1, \dots, F_\bullet^r$ in \mathbb{R}^N , what is the cardinality of

$$\left| \bigcap_{j=1}^r \sigma_{\lambda_j}(F_\bullet^j) \right| = ?$$

for $\sigma_j := \sigma_{\lambda_j}$ of total dimension $\text{Gr}_{2k}(\mathbb{R}^{2n})$?

The word generic is a subtle point here: we will say that the flags are *generic*, if the corresponding Schubert varieties are transversal. This is an open condition in the configuration space by the Kleiman-Bertini theorem. The main property of generic configurations \mathcal{G} relevant to us is that the number of solutions is locally constant on \mathcal{G} .

In the complex case $\mathbb{F} = \mathbb{C}$, a Schubert problem can be solved by multiplying Schubert cycles: since everything is complex, at a smooth transversal intersection all tangent spaces have canonical orientations, therefore all intersections come with the same sign. Therefore the cohomology product of $[\sigma_j]$ is an element $n[*]$ of $H^{\text{top}}(\text{Gr}_k(\mathbb{C}^n)) \cong \mathbb{Z}\langle[*]\rangle$, and this number n is the answer to the Schubert problem.

In the real case $\mathbb{F} = \mathbb{R}$, there are no canonical orientations, therefore each transversal intersection p comes with a sign, depending on whether the orientation of the tangent spaces $T_p\sigma_j$ agrees with the orientation of the tangent space $T_p\text{Gr}_k(\mathbb{R}^n)$. Therefore the cohomological calculation only gives a signed sum of the points, hence a lower bound to the Schubert problem. The actual number of solutions depends on the configuration (the choice of the flags F_\bullet^i), and there is a range of numbers that might appear as the number of solutions. This range is not known in general, and it has been subject to extensive examination, see [34,48,49]. An infinite series of examples has been computed via elementary methods in the case of Grassmannians in [18]. For example, in $\text{Gr}_8(\mathbb{R}^{16})$ the number of solutions to the Schubert problem σ_λ^4 for $\lambda = (4, 4, 4, 4)$ can be $\{6, 14, 30, 70\}$, see [18]. Recently, similar problems were considered for Grassmannians using Chow-Witt rings [57].

The dependence of the number of solutions on the given configuration has the following explanation. In the complex case, the singular configurations form an at least one complex codimensional subvariety of the configuration space, so the space of nonsingular configurations is connected. In the real case, the singular configurations can be one *real* codimensional, in which case the configuration space falls apart into connected components (*chambers*).

An upper bound for the range is given by the number of solutions for the corresponding generic complex Schubert problem. Here some caution is required when discussing genericity: one has to show that there exist real generic flags which are complex generic when regarded as complex flags. Indeed, this is the case: the subset of complex nongeneric configurations can be defined by real equations, so there exist real flags F_\bullet^j which are complex generic. For such flags, all intersections of $\sigma_j^{\mathbb{C}}(F_\bullet^j)$ are transverse, therefore so are those of $\sigma_j^{\mathbb{R}}(F_\bullet^j)$, so such configurations are also real generic.

It is a natural question, whether a real enumerative problem is *maximal/fully real* [49], i.e. whether there exists a configuration for which the number of solutions agrees

with the number of solutions for the same complex problem. This is true for real Schubert problems in Grassmannians as shown in [53].

Another natural question in real enumerative geometry, is to find a lower bound for the range of solutions [33,56]. For example, by a Theorem of Segre, there are at least 3 lines on a cubic surface [43], more generally there are at least $(2n - 1)!!$ real lines on a degree $2n - 1$ hypersurface in $\mathbb{R}P^{n+1}$ [21]. For a lower bound on the number of 3-planes on an appropriate degree hypersurface see [20, Theorem 4.1.3]. See [39] for examples of enumerative problems with a strict lower bound of zero, i.e. no real solutions. As we have already mentioned, for Schubert calculus the cohomology calculation also gives a lower bound. By the description of the real Littlewood-Richardson coefficients (Corollary 4.5) we have:

Proposition 7.1 *The number of solutions of a double real Schubert problem $(D\lambda_j)$ is bounded below by the number of solutions to the half sized complex one (λ_j) .*

This means that any complex Schubert problem can be “doubled”. We illustrate this via three examples.

Example 7.2 How many real 6-planes in \mathbb{R}^{12} intersect 9 given 6-planes in at least 2 dimensions?

This problem can be written as \boxplus^9 in $\text{Gr}_6(\mathbb{R}^{12})$. By the previous Proposition, a lower bound is given by the half-sized complex problem, namely \square^9 in $\text{Gr}_3(\mathbb{C}^6)$. This in turn is equal to the degree of $\text{Gr}_3(\mathbb{C}^6)$ via the Plücker embedding, which is 42; this is known in general, see e.g. [28, p. 247]. So the answer is 42: there are at least 42 such real 6-planes.

Example 7.3 How many real 8-planes in \mathbb{R}^{14} intersect 6 given 8-planes in at least 4 dimensions?

This problem is

in $\text{Gr}_8(\mathbb{R}^{14})$. Again, a lower bound is given by the half-sized complex problem, namely \boxplus^6 in $\text{Gr}_4(\mathbb{C}^7)$. A computation using the Pieri rule and duality shows that the answer to the complex problem is $\boxplus^6 = 16$. So the real problem has at least 16 solutions.

Example 7.4 We also give an example which uses the product structure on flag manifolds. Given the following ten generic subspaces in \mathbb{C}^5

$$E_1^i, E_3^i, \quad i = 1, 2, \quad \text{and} \quad E_2^j, E_4^j, \quad j = 1, 2, 3,$$

of dimension $\dim(E_i^j) = i$, how many complete flags F_\bullet in \mathbb{C}^5 satisfy the following conditions:

- $E_1^i \subseteq F_4$ and $\dim F_2 \cap E_3^i = 1$ for $i = 1, 2$,
- $F_1 \subseteq E_4^j$ and $\dim F_3 \cap E_2^j = 1$ for $j = 1, 2, 3$.

This corresponds to the product of special Schubert classes in $H^*(\text{Fl}(\mathbb{C}^5))$

$$[\sigma(4)]^2[\sigma(2)]^2[\sigma(1)]^3[\sigma(3)]^3 = 7$$

where we denote by $\sigma(i)$ the one codimensional Schubert variety corresponding to the transposition $(i, i + 1)$. This problem then can be doubled: Given the following generic subspaces in \mathbb{R}^{10}

$$E_1^i, E_3^i, \quad i = 1, 2, \quad \text{and} \quad E_2^j, E_4^j, \quad j = 1, 2, 3,$$

of dimension $\dim(E_i^j) = 2i$, how many flags F_\bullet in $\text{Fl}_{\mathcal{D}}(\mathbb{R}^{10})$, $\mathcal{D} = (2, 2, 2, 2, 2)$ satisfy the following conditions:

- $E_1^i \subseteq F_4$ and $\dim F_2 \cap E_3^i = 2$ for $i = 1, 2$,
- $F_1 \subseteq E_4^j$ and $\dim F_3 \cap E_2^j = 2$ for $j = 1, 2, 3$.

Using Proposition 7.1, the complex answer implies that this problem has at least 7 solutions. $\text{Fl}(\mathbb{C}^5)$ was the smallest flag variety that we found with a nontrivial Schubert problem that cannot be reduced to the case of Grassmannians.

As we have seen, the cohomology of real Grassmannians (and even flag manifolds) with integer coefficients contains only 2-torsion. If in a Schubert problem all Schubert varieties are cycles, but one of them is \mathbb{Z}_2 -torsion, then the corresponding cycles multiply to zero in cohomology (at least if the flag manifold is orientable), which is a trivial lower bound. Note however that the corresponding Schubert problem can be, and usually is nontrivial. There exist enumerative problems, which do not have any cohomological interpretation: the corresponding Schubert varieties are not cycles. For example, dual transversal Schubert varieties always intersect in one point, and not all Schubert varieties are cycles. Summarizing: for the purpose of obtaining enumerative lower bounds, we don't lose anything by working with rational coefficient cohomology.

Alternatively, considering \mathbb{F}_2 -coefficient cohomology, one can apply the original Borel-Haefliger theorem [7] to Grassmannians to obtain mod 2 information about a Schubert problem:

Proposition 7.5 *The number of solutions of a real Schubert problem has the same parity as the number of solutions of the corresponding complex Schubert problem.*

For certain Schubert problems, one can say more than mod 2 congruence of the solutions, see e.g. [18, Theorem 5.7] and [34]. We conclude with a conjecture:

Conjecture 7.6 *The lower bound of Proposition 7.1 is sharp.*

We make some remarks on this conjecture. Take real complete flags $F_\bullet^j \in \text{Fl}(\mathbb{R}^n)$, such that F_{2i}^j are $U(1)$ -invariant. Then the set of solutions

$$S := \bigcap_j \sigma_{D_{I_j}}^{\mathbb{R}}(F_\bullet^j)$$

is a $U(1)$ -invariant subset. If S is finite, then each point $W \in S$ is a $U(1)$ -fixed point, i.e. complex. Therefore, each $W \in S$ is a solution to the corresponding half sized complex Schubert problem

$$W \in S_{\mathbb{C}} = \bigcap_j \sigma_{I_j}^{\mathbb{C}}(F_{\bullet, \mathbb{C}}^j),$$

so this problem has exactly as many solutions as the half sized complex Schubert problem. However, it is not clear to us whether such a problem is real generic, which is required in order to show that this is a sharp lower bound. This reduces the conjecture to one about genericity: Does there exist a complex generic configuration of flags $F_{\bullet, \mathbb{C}}^j$, which as real flags $F_{\bullet, \mathbb{R}}^j$ are real generic (for the double sized real problem)?

Acknowledgements This paper is based on the author's PhD thesis [41]. I am grateful to my PhD supervisor László M. Fehér for many valuable discussions and helpful comments that improved the quality of this paper. I thank Liviu Mare for several discussions on the topics of this paper. I am grateful to the anonymous referees for carefully reading the manuscript and for their suggestions, which greatly improved the presentation of the paper.

Appendix A. Topology: Cartan model

A pair (G, K) of compact connected Lie groups is a *Cartan pair*, if $K \subseteq G$ is a subgroup and H_G^* is a polynomial ring in $\text{rk } G$ many generators, $\text{rk } G - \text{rk } K$ many of which restrict to zero via $\rho^* : H_G^* \rightarrow H_K^*$.

For Cartan pairs, there is a simple description of $H^*(G/K; \mathbb{Q})$, due to Cartan and Borel [5], see also [51] for a summary.

Theorem A.1 (Borel, Cartan) *For a Cartan pair (G, K)*

$$H^*(G/K; \mathbb{Q}) \cong H_K^* / (\text{Im } \rho^*)_+ \otimes \bigwedge [x_{r_i-1}]_{i=p+1}^n$$

where r_i are the degrees of the polynomial generators restricting to zero via $\rho^* : H_G^* \rightarrow H_K^*$, $n = \text{rk } G$, $p = \text{rk } K$, $\deg x_j = j$ and $(W)_+$ denotes the ideal generated by elements of positive degree of the subspace W .

Let $SO(\mathcal{D}) := \prod_{i=1}^m SO(d_i)$, $O(\mathcal{D}) := \prod_{i=1}^m O(d_i)$ $N := \sum d_i$.

Proposition A.2 $(G, K_0) = (SO(N), SO(\mathcal{D}))$ is a Cartan pair for all \mathcal{D} .

Proof One has

$$\rho^*(p_*(S)) = \prod_{i=1}^m p_*(S_i),$$

where $S \rightarrow BSO(N)$ and $S_i \rightarrow BSO(d_i)$ denote the tautological bundles and p_* denotes the total Pontryagin class. Let $n = \lfloor \frac{N}{2} \rfloor$ be the rank of $SO(N)$ and $q = \sum_{i=1}^m \lfloor \frac{d_i}{2} \rfloor$ be the rank of $SO(\mathcal{D})$. Since $p_{\text{top}}(S_i) = p_{\lfloor \frac{d_i}{2} \rfloor}(S_i)$, by examining degrees, one sees that $\rho^*(p_j(S)) = 0$ for $j > q$. □

The real flag manifold is a homogeneous space $\text{Fl}_{\mathcal{D}}^{\mathbb{R}} = G/K$, where $G = SO(N)$ and $K = S(O(\mathcal{D}))$. Since K is not connected, the Borel-Cartan model cannot be directly applied. $H^*(G/K; \mathbb{Q})$ was recently determined by He in [32], we state the theorem, also to be found in [41].

Let $\mathcal{D}_0 = (\lfloor d_1/2 \rfloor, \lfloor d_2/2 \rfloor, \dots, \lfloor d_m/2 \rfloor)$. Since there is a covering $\Gamma \rightarrow G/K_0 \rightarrow G/K$ for $\Gamma = \mathbb{Z}_2^{m-1}$, $H^*(G/K) = (H^*(G/K_0))^{\Gamma}$. The Γ -action acts by multiplying the Euler classes in H_K^* by -1 and trivially on the Pontryagin classes and on the exterior algebra, for further details see [32] or [41].

Theorem A.3 Let $n = \lfloor \frac{N}{2} \rfloor$ be the rank of $SO(N)$ and $q = \sum_{i=1}^m \lfloor \frac{d_i}{2} \rfloor$ be the rank of $SO(\mathcal{D})$, then

$$H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Q}) \cong H^{2*}(\text{Fl}_{\mathcal{D}_0}^{\mathbb{C}}; \mathbb{Q}) \otimes \bigwedge [y_i]_{i=q+1}^n$$

where $y_i = x_{4i-1}$ except if N even, $y_n = x_{N-1}$. H^{2*} means that the degrees are doubled and $\deg x_j = j$. The first term H^{2*} is generated as an algebra by $p_i(D_j)$ with the relations given by the identity $\prod_{j=1}^m p_*(D_j) = 1$.

Appendix B. Schubert cycles: the general case of partial flag manifolds

Using the coefficients of the Vassiliev complex described in Section 3, we computed some of the generators of $H^*(\text{Fl}_{\mathcal{D}}^{\mathbb{R}}; \mathbb{Q})$ in terms of Schubert cells using SageMath’s homology package [52]. We include below some cases which are not covered by Theorems 3.12 and 5.1, in particular, complete, odd and other examples. As previously mentioned, for general $\text{Fl}_{\mathcal{D}}$ it is no longer true that rational cohomology classes can be represented by Schubert varieties, but a signed sum of Schubert cells. The choice of the generators are not unique, as we already saw on the example of $\text{Fl}(\mathbb{R}^4)$, Section 3.10. In all the examples we have computed, the coefficients of these Schubert cells are ± 1 . In the tables, we use the following conventions.

Notation. The Schubert cells $\Omega_I \subseteq \text{Fl}_{\mathcal{D}}$ are parametrized by ordered set partitions $I \in \text{OSP}(\mathcal{D})$. These are denoted by the one-line notation of their minimal representatives: elements of I_j are listed in increasing order, I_j and I_{j+1} is separated by a

comma. The + sign separates the Schubert cells whose sums are generators. We do not keep track of the sign of the cells, as this can vary according to convention (even though relative to each other, the signs do make sense). In the last table, the ordered set partitions are elements of $1, 2, \dots, 11$; for typographical reasons 10 and 11 are preceded by a space.

B. 1. The complete case

The two extreme cases of real flag manifolds are Grassmannians and complete flag manifolds. We understand the Schubert calculus of Grassmannians by Propositions 5.2 and 5.3. For the case of complete flag manifolds, the answer appears to be less simple, as we illustrate in Tables 2 and 3. For the case of $Fl(\mathbb{R}^3)$ see also [38, p. 5] and for $Fl(\mathbb{R}^4)$, see also [12, p. 529].

B. 2. The odd case

There are two cases when flag manifolds $\text{Fl}_{\mathcal{D}}^{\mathbb{R}}$ are orientable; all d_i are even or all odd. If all d_i are even, we understand the generators of rational cohomology by Theorem 3.12. If all d_i are odd, the answer again appears to be less simple, see Tables 4 and 6 (and also the complete cases).

B. 3. The other cases

See Table 5 for a nonorientable case.

Table 5 Sums of Schubert cells generating $H^*(\text{Fl}_{234}; \mathbb{Q})$, labeled by $\text{OSP}(2, 3, 4)$

31	123,49 10,5678 11
31	147,238,569 10 11+167,234,589 10 11
35	145,236,789 10 11
35	123,478,569 10 11
39	123,456,789 10 11

These examples hopefully illustrate that although there is a simple description of the cohomology of real flag manifolds in terms of topology (cf. Cartan model, Appendix A), in general there is some nontrivial combinatorics involved in translating that description to the Schubert calculus setting.
