(Received: 29 January 2021; Accepted: 3 January 2022)

The paper presents new records of *Taraxacum parnassicum*, the most common member of *Taraxacum* section *Erythrosperma* in Slovakia. The species has been recorded in most of the 31 phytogeographical districts of Slovakia. At least 25 new localities were discovered, and many old ones were confirmed. *T. parnassicum* prefers natural and semi-ruderal sites on limestone, rarely on volcanic and sandy soils, predominantly not shaded. The majority of populations occur from the lowland to supracolline vegetation belt, mainly at elevations of 140–700 m a.s.l., with the altitudinal maximum at 1,410 m a.s.l. A distribution map is given with the list of localities from the whole territory of Slovakia as well as short discussion about its taxonomy and ploidy level.

Key words: apomixis, Central Europe, chorology, lesser dandelion

INTRODUCTION

The third part of our series dealing with revision of chorology of *Taraxacum* section *Erythrosperma* in Slovakia focuses on the species *Taraxacum parnassicum*. It follows up previous studies on *T. cristatum* Kirschner *et al.* (Dudáš 2019) and *T. danubium* A. J. Richards (Dudáš *et al.* 2020a).

The species is usually a delicate plant with remarkable (and relatively unique) determination characteristics making this beautiful taxon popular even among non-specialists. It is one of few *Taraxacum* species widely recognised by botanists. For a long period, it was widely known as *Taraxacum silesiacum* G. E. Haglund, and under this name majority of publications were published. Evaluation of Dahlstedt's original material of *T. parnassicum* Dahlst. by H. Øllgaard led to synonymising of *T. silesiacum* with *T. parnassicum* (Lundevall and Øllgaard 1999). According to Doll (1973) it belongs to *T. silesiacum* group together with other 8 species. However, taxa listed by Doll are probably only superficially similar (besides *T. badium* now synonymous with *T. parnassicum*) and probably do not share true relationship.

Although the genetic relationship to other European taxa of lesser dandelions is still unknown, some Central European species are superficially similar. However, it has several very remarkable morphologic characters, making the species easily recognisable from such species. In Central Europe, it can be misidentified with young plants of *T. danubium*, *T. rubicundum* (Dahlst.) Dahlst. or *T. arcuatum* (Tausch) Dumort. The most remarkable difference from these three superficially similar taxa is the absence of pollen grains, which also cause that capitulum is flat in *T. parnassicum* (on the contrary to distinctly convex capitula of other taxa). Another very remarkable characteristic is the acute triangle terminal lobe, all three mentioned taxa have terminal lobe more or less obtuse (Fig. 1). Lateral lobes of *T. parnassicum* are usually simple, they are deltoid and regularly arranged, usually not having any distinct tooth on their margins (as it is usually present on distal margin of lateral lobes in *T. rubicundum* and *T. arcuatum*), and never distinctly blunt at the tip as it is in *T. danubium*. The involucrum of *T. parnassicum* has irregularly broad inner involucral bracts, which is quite unique among Central European taxa of lesser dandelions (besides the species, it is known only in one other, yet undescribed species of the *T. proximum* group and that differs by longer outer bracts and different shape and colour of achenes). The species is remarkable by its later phenology, flowering circa 1 (or 2) week(s) later than most of lesser dandelions in Central Europe. Achenes are dark violet-brown, but remarkably brick-red when immature (e.g. Reisch and Schmid 2001, Šuvada *et al.* 2012, Vašut 2003).

The species is a triploid apomictic microspecies with a chromosome number $2n = 3x = 24$. The triploid chromosome number was previously reported by Májovský *et al.* (1970, 1974), Marhold *et al.* (2007), Richards (1970) and Šuvada *et al.* (2012). This was further confirmed by flow-cytometric meas-

Fig. 1. *Taraxacum parnassicum*. General habitus of live plants (left) and details on herbarium specimen (right), a = deltoid and regularly arranged lateral lobes, b = clustered terminal and neighbouring lobes and c = absence of tunica (Orig. M. Dudáš)

urements (Dudáš *et al.* 2013, Šuvada *et al.* 2012). Chromosome counts and ploidy level from Slovakia correspond to those from other parts of Europe, e.g. Czechia (Trávníček *et al.* 2010, Vašut 2003), Germany (Uhlemann 2000), Poland (Małecka 1969, Wolanin and Musiał 2017), the Netherlands (den Nijs *et al.* 1978) and Great Britain (Dudman and Richards 1997).

Dahlstedt described the species based on the material cultivated from seeds, which originated from Mt Parnassos in Greece (Dahlstedt 1926). Haglund (1938) described species *T. silesiacum* (based on Dahlstedt's unpublished work) from the vicinity of nowadays city Legnica in Poland [Liegnitz in Silesia]. Species is recently known from major part of Europe (e.g. Aquaro and Peruzzi in Conti *et al.* 2007, Doll 1973, Dudman and Richards 1997, Mosyakin and Fedorovichuk 1999, Richards 1991, Sell and Murrell 2006, van Soest 1957, Wendt 2001, Wendt and Øllgaard 2015) and is considered a common species especially in Central and Southern Europe (see e.g. in Kallen *et al.* 2003, Sackwitz *et al.* 1998, Štěpánek and Kirschner 2012, 2014, Uhlemann 1996, 2003, Vašut 2003, Wolanin and Musiał 2017, and many floristical records cited in these publications). Records from Slovakia are scarce and yet provided only incomplete overview of its distribution in the territory (Dudáš *et al.* 2020b, Kirschner and Štěpánek 1995, Májovský *et al.* 1970, 1974, Richards 1970, Šuvada 2010, Šuvada *et al.* 2012).

Some authors observed its regional preference for calcareous substrates (e.g. Reisch and Schmid 2001, 2002, Schmid and Horn 1995), but it was not observed as general phenomenon and other authors observed its distribution ecologically broader and not narrowly limited to such habitats (e.g. Uhlemann 1996, 2003, Vašut 2003).

The aim of this study was to provide detailed information on distribution of *T. parnassicum* in Slovakia, based on our intensive study of Slovak dandelions by field observations and revision of herbarium specimens from public herbaria collections.

MATERIAL AND METHODS

The study was carried out during the years 2008–2020. We used only revised herbarium sheets and own collected material from the field research to determine the species distribution in Slovakia. The data were obtained from the public Central European herbaria including: BBZ, BP, BRA, BRNM, BRNU, HLO, HNTS, KO, LTM, MOP, NI, OL, OLM, PL, PMK, PR, PRC, SAV, SLO, SMB, SMBB, SNV, TM, ZAM, ZV and Richard's type collection deposited in Great Britain (OXF). The herbarium abbreviations are according to Thiers (2020+) and also Vozárová and Sutorý (2001) for small local museum collections. Results of this study are presented on the dot map designed by the program ArcGIS, version 9.2. The grid on the map follows the one described by Niklfeld (1971). The list of localities was compiled according to recommen-

dations of Flóra Slovenska, which we applied in our previous studies (Dudáš 2019, Dudáš *et al.* 2020a).

The ploidy level was detected by flow-cytometry following previously published work (Koprivý *et al.* 2019).

RESULTS AND DISCUSSION

Distribution in Slovakia

Taraxacum parnassicum has a scattered distribution in Slovakia (Fig. 2). The presence of the species was recorded in 7 and 23 phytogeographical districts and subdistricts of the Pannonic (Pannonicum) and Carpathian (Carpathicum) biogeographical regions, respectively. Although it seems it has large distribution, the species is not very frequent at many localities. It predominantly occurs on calcareous type of substrates (limestone, dolomite and travertine) in Slovakia (Fig. 3), but occasionally it was found on sandy or volcanic substrates. This is in contrast with the wider ecological claims of *T. cristatum* (Dudáš 2019) or *T. danubium* (Dudáš *et al.* 2020a), which do not strictly prefer calcareous substrates.

Characteristic of Taraxacum parnassicum populations in Slovakia

The ploidy level of *T. parnassicum* is known to be triploid (Dudáš *et al.* 2013, Májovský *et al.* 1970, 1974, Marhold *et al.* 2007, Richards 1970 and Šuvada

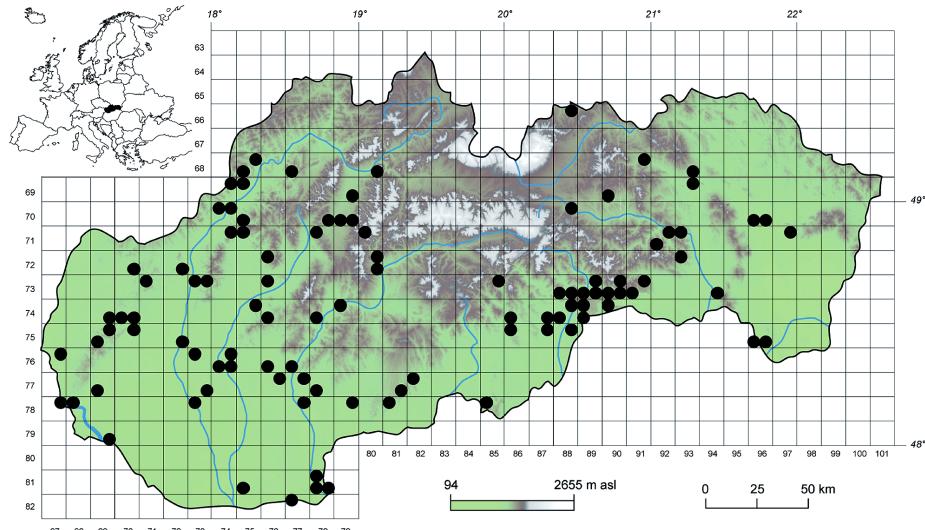

Fig. 2. The overall distribution of *Taraxacum parnassicum* in Slovakia (black dots)

et al. 2012). We additionally confirmed it by flow-cytometric measurement of plants from the Spišský hrad castle hill, having the $2C = 2,716$ pg ($2n \sim 3x$).

Taraxacum parnassicum often prefers semi-ruderal sites in natural steppe grasslands in Slovakia. It often grows along pathways and field roads in dry grasslands or pastures, but also in light and open forests (mostly oak forests, less frequently hornbeam or locust woods). Especially frequent occurrence is along pathways in hilly cultural sites (recently touristic hotspots), which have been deforested for centuries, such as castle hills, chapels, churches, calvaries, sightseeing towers and similar. In most cases it grows on limestone and travertine substrates, rarely on other types of substrates.

This microspecies occupies a wide range of altitudes from the Pannonian lowlands to the Carpathian mountain beech zone. The highest documented occurrence was found at 1,410 m a.s.l. in the Veľká Fatra Mts on the top of the hill Bágl'ov kopec (collected by D. Bernátová in 1976, voucher specimen deposited in BBZ, revised by J. Štěpánek, published in Kliment 2008: 280) and near the rock at Kráľová studňa in ca 1,340 m (for details see Appendix). The lowest elevations of its occurrence were noticed at about 125 m a.s.l. in the southern part of the lowlands Východoslovenská nížina and Podunajská nížina.

Different types of biotopes of *T. parnassicum* in Slovakia: Zemplínske vrchy Mts, Lámovské vápence Nature reserve, middle grassy belt of field road (A), Beskydské predhorie hill area, castle Brekovský hrad, tourist paths towards castle ruins, *Festucetum valesiacae* (B), Nízke Beskydy hill area, Demjatské kopce Nature reserve, calcareous rocky places (C) and Slovak Karst, plain Silická planina, limestone karst areas (D) (Photo: M. Dudáš)

CONCLUSIONS

The article presents the results of study of chorology and ecology of *Taraxacum parnassicum* in Slovakia. It is the third part of small series dealing with revision of lesser dandelions in the territory of Slovakia.

*

Acknowledgements – We are grateful to J. Štěpánek (Průhonice, Czechia) for the determination of herbarium material, V. Kolarčík (Košice, Slovakia) for the detection of ploidy level of living plants and L. Mártontfiová for the correction of English language. Thanks are also due to all colleagues who helped me in the field course and to M. Marcinčinová (Košice, Slovakia) for graphical help. This study was supported by internal grant VVGS-PF-2018-751 (MD).
