Abstract

The work presented here is part of a larger study that looks at the impact that structured teaching materials have on improving orthographic skills. The first step is an analysis of the current status of linguistic structures in common primary readers (primers) since their key purpose is to lead children along a systematic learning path towards becoming proficient readers and writers. Using text processing tools detecting morphemes, syllables and sentence structures, several popular primers are automatically examined with respect to their systematic approach to language at the phonics/syllable, word and sentence levels. It can be shown that there is little apparent structure in today’s school texts at any of the examined levels when compared to some older schoolbooks (1877, 1904) that have a systematic and explicit progression at all examined levels.

1 Introduction

Over the last decade the number of children in Germany referred to language pathologists (Logopädie) has increased manifold according to WiDO AOK (health insurance) (2012; 2013) to reach an all-time high of 25% for boys aged around six. The cause for this phenomenon has not been well studied. Our hypothesis is that an improved structure in learning materials at the word and sentence level may improve orthographic skills. As a first step towards answering this question, this paper looks at the given structure in popular first grade readers (primers). To study the actual impact of structure on performance is beyond the scope of this paper but has been covered in part by other publications in this series of work (Berkling and Pflaumer, 2014; Berkling et al., 2015). This line of research is further motivated by results stemming from a large-scale analysis of orthographic skills in a corpus from first grade until eighth grade. In order to understand why certain spelling errors persist, more analysis is clearly needed to show the impact of teaching methods on acquisition of orthography.

Much work has been done in studying various approaches for English reading and writing acquisition. The National Reading Panel (Donald N. Langenberg et al, 2000) and more up-to-date studies by Galuschka (2014) have published meta-reviews of major comparative and quantitative studies, realizing that phonics is a vital component in reading instruction. It has been shown in the Anglophone research by Stahl (1989) that relying solely on the whole-word approach is to the detriment of the weaker students. It has also been shown by Steffler (2001) that making structure explicit leads to efficient learning results. To our knowledge, no comparative work has been done on the German language. Phonics in its complexity is also not known as a method for reading/writing acquisition in Germany. In that sense, phonics is not apparent in the elementary readers while other methods prevail.

Currently, in Germany, there are mainly 2-3 popular methods in use. One such method is called “Lautiermethode” and refers to the theory that words can be sounded out one letter at a time (Reichen, 2008; Brügelmann, 2014). By synthesizing the sounds, the word is supposed to be read in its entirety. This works approximately for words like “Oma” or “Banane” that is an imported word but deemed “lautgetreu”, meaning one grapheme corresponds to one phoneme. However, this approach fails to generalize to typical German structures in which a single grapheme <e> can stand
for at least three semantically distinct pronunciations as a function of its position within syllable and word.

Another popular method says that reading acquisition takes place at the syllable level as this is more natural for children to bridge from the spoken language to the written representation (Röber-Siekmeyer, 2004). However, if the syllables are not taught well, then the learner pronounces the unstressed syllable in a stressed manner, thereby not recognizing the sound of the resulting word, for example by reading ”Mutter” as /mut:ter/ instead of /mut/.

Finally, the whole word approach is widely used, even if not explicitly stated. It assumes that the child, given enough practice, will memorize the words as a unit. In general, experts say that first grade learning and teaching is based on a mix of all these methods and their respective effectiveness is child dependent.

Primers (Fibel in German) for first grade traditionally have the primary purpose of leading children in a systematic manner towards learning to read and write. As a first step towards understanding these methodologies and their progression, the goal of this work is to analyze and document selected structures and their progression in primary readers. The analysis looks at the lexical level through syllable and morpheme occurrence, word structures at the syllable level and complexity progression at the sentence level. Texts are analyzed for a number of books, including two older ones from 1877 and 1904 that show explicit structure unlike any of the ones used today.

The rest of the paper proceeds as follows. Section 2 motivates the proposed levels of analysis. After a brief overview of German phonics system and sentence complexity levels in Section 3, Section 4 will explain the tools used for analysis. Section 5 will introduce the data and Section 6 reports on the results, comparing the various different texts. Section 7 discusses the results.

2 Motivation

Elementary primers have traditionally had the purpose of serving as a guide for learners of a reading and writing system. In this function, they should naturally display a thought-out systematic approach on how they move from simple towards increasingly complex materials, considering the problem of inert knowledge (what children theoretically know but are unable to use) which can be reduced by usage in different contexts (Bereiter and Scardamalia, 1985).

When looking at old primers, this type of progression is often made explicit within the index or names of the chapters as shown in Figure 1. Today’s books do not explicitly have a progression apart from the order of introduction of the graphemes. The goal of the work presented here is to visualize and render explicit any inherent progression that can be found at the syllable, morpheme or sentence structure level, keeping in mind that a systematic approach, including explicitness is important according to a study by Steffler (2001) to ensure the learners’ grasp of linguistic structures. Finally, a look at progression should include a look at the complexity that can be reached.

It is well known, that learning builds on previous knowledge and that each new material should have small consecutive steps building on each other (Martin and Rose, 2005; Leong, 1998). As a consequence, complexity grows incrementally and builds on the knowledge of the preschooler, which is mostly based on syllable structure of the language and progresses from there as described by Siekmeyer (2009).

For the German language, the most common syllabic pattern is the "Trochee" type of word.
(2-syllable length, first syllable stressed, second one unstressed). A comparable example for both English and German is the word "double" or "doppelt". The top 10,000 German words in newspapers include about 16% of pure 2-Syllable Trochees that follow this pattern. The 100 most used words cover around 45% in a standard text. The rest of the words are constructed words, such as compound words or those containing prefix or suffix attached to words that contain the Trochee pattern, where students have to generalize the pattern to unseen words – these make up about 45% of the top 10,000 words according to an automated analysis by Berkling (2014).

The remaining words, like "Auto", "Banane", "Tiger", "Portemonnaie" are imported vocabulary and follow different orthographic patterns that are not directly comparable to German. This is why the study of the Trochee is at the center of the word-pattern analysis.

Research questions to answer by analyzing the data are therefore the following: 1) Are the patterns of the German language (in form of Trochee) occurring in some structured form? 2) Is there repetition at syllable and morpheme level to support the cognitive process by achieving automation as described by McLaughlin (1990)? 3) Is the vocabulary embedded within sentence structures that exercise grammatical structures, including morpheme endings?

3 The Structure of German Text

In this section, the underlying theory concerning syllable types for the German language is explained. The structures underlying the study of word repetition and sentence complexity are also thereby defined and motivated.

3.1 Syllables

The German language distinguishes between three major classes of Trochee that will be described next.

- **Type 1: C-V-C-red ("b-e-t-en")**: This type of Trochee is the simplest form (phonemes: Consonant-Vowel-Consonant-reduction), comparable in that sense to the "cat", "hat", "mat" vocabulary used in the first steps of English phonics lessons. The 1-syllable form CVC derives directly from the 2-syllable Trochee ("gab" – as past tense of "geben"). In this case, the morpheme boundary is within the Trochee. CVCred can not be reduced to a 1-syllable words when there is no morpheme boundary within the Trochee, examples are "bird" ("Vogel") or "vase" ("Vase"). Identifiable features of this word type are the tense/long vowel (V) followed by a single consonant sound and a reduction syllable that contains the letter <e> pronounced as schwa /ə/.

- **Type 2: C-v-C1-red ("B-e-tt-en")**: The second type of word is one of the most difficult features of the written language to master by learners of the orthographic system (phonemes: Consonant - short vowel - Consonant - reduction). It distinguishes itself from the first type only by the feature tense/lax of the vowel, perceived as shortness in this form. As in the first type, there is only one consonant sound in the center of the word. However, in the orthography the tenseness of the preceding vowel is denoted by duplicating the center consonant letter. Orthographically, there are regularities such as <tt>, <nn> and irregularities such as <ng>, <tz>, <ck>, or <sch> and <ch> that need to be mastered. The 1-syllable form CvC1 derives directly from the 2-syllable Trochee ("Betten" (plural) – "Bett" (singular)). In this case, the morpheme boundary is within the Trochee. Not all CvC1red will reduce to 1-syllable words, such as the word for "rattle" ("Rassel"). Identifiable features of this word type are the lax/short vowel (v) followed by a single consonant sound and a reduction syllable containing the letter <e> pronounced as schwa /ə/.

- **Type 3: C-v-C1-C2-red ("r-a-s-t-e-n"):** The third type of word is easier than the second one for the learner, as there are two distinct consonant sounds in the center of the word to help denote the tenseness of the preceding vowel. No orthographic particularities need to be mastered. The 1-syllable form CvC1C2 derives directly from the 2-syllable Trochee ("rasten" (verb) – "Rast" (noun)). In this case, the morpheme boundary is within the Trochee. Not all CvC1C2red will reduce to 1-syllable words, such as the word for turn: "Wende". Identifiable features of this word
type are the lax/short vowel (v) followed by two consonant sounds and a reduction syllable containing the letter <e> pronounced as schwa /ə/.

- **Other categories** of words include foreign words and high-frequency words as well as constructed words (compound words and those including prefix and suffix). These are not considered separately for the purpose of this study as they decompose either into the aforementioned formats or do not pertain to German phonics rules.

### 3.2 Sentences

There are numerous publications regarding the definition of sentence readability (Glöckner et al., 2006; Sitbon and Bellot, 2008; DuBay, 2008). Nelson (2012) is an example of a recent overview of such measures. Most of them have been designed for English. Regarding German language, little research has been done on that subject. We can cite (Hancke et al., 2012) where the authors used a number of different features to determine sentence readability: average number of words, characters, syllables, lexical features (noun and verb token ratios, textual lexical diversity, ...), syntactic features (number of noun or verb phrases, average length of a noun phrase, ...), language models (trained with texts for children vs. newspapers) and morphological features (ratio of finite verbs, compounds, ...).

However, the goal of the study presented here is not exactly to measure a sentence readability, but to describe the progression in the structures’ complexity (word-level clues are considered separately, as described in Subsection 3.1). Hence, for the purpose of written language acquisition a progression as described by Clahsen (1982; 1988) for L1 acquisition in children is chosen as a first approach. (A more detailed analysis of sentence structures can be found in Berkling (2014)). For the purpose of this study, sentence structures are distinguished at the following levels:

- **LEVEL 1**: One-word utterances without counting articles, so it covers simple noun phrases such as "Peter" and "eine Katze" (a cat) and imperative verbs "Lauf!" ("Run!").

- **LEVEL 2**: Two-word utterances without counting articles, so simple noun phrases (as described for level 1) + Verb in present tense ("Peter isst" ("Peter is eating"). "Eine Katze läuft" ("A cat is running") or noun phrases including adjectives not followed by a verb: "die kleine Katze" ("the little cat").

- **LEVEL 3**: Common sentences, including Adjectives, Adverbs, ... So, noun phrases (including complex ones, such as article + adjective + noun) + Verb with or without Object: "Die kleine Katze." ("the little cat."). "Die kleine Katze läuft" ("The little cat is running"). "Ich gehe nach Hause" ("I am going home").

  - past and future tenses, built with a conjugated auxiliary (2nd position) and an infinitive (future) or past participle (past tense) form of the meaningful verb, located at the end of the sentence: "Wir werden nächsten Sommer nach Spanien fahren". ("We will go to Spain next Summer"). "Du hast spät in der Nacht gearbeitet". ("You have worked late in the night").

  - modal verbs: used to express obligation, ability or will. These verbs are conjugated and located in the second position in the sentence, then the verb on which the modality applies is located at the end of the sentence: "Du sollst morgen nicht kommen" ("You should not come tomorrow").

  - compound verbs: conjugated verb is in 2nd position, the particle is at the end of the sentence: "Die Sonne geht immer früher auf" ("The sun rises earlier and earlier") – The compound verb "aufgehen" (to rise) has a different meaning than the verb "gehen" (to go).

- **LEVEL 5**: complex sentences. Depending on the kind of clause, verb positions follow different rules. Thus, we have distinguished two subcategories, to reflect different complexities: the coordinate considered as an independent sentence, where the verb is located in 2nd position (in both of the clauses). e.g., "Ich bin fertig und ich gehe jetzt in die Schule" ("I am ready and I go to the school now"), or in subordinate clauses with the verb located at the end of the subordinate clause: "Ich denke, dass er intelligent ist" ("I think that he is smart").
Sentence containing several levels are classified as the highest: "Ich werde ein Buch kaufen, weil ich viel lese." ("I will buy a book, because I read a lot.") – is thus considered as Level 5.

4 System

Three software modules as shown in Figure 2 are built to analyze the primary reader texts. A synthesizer, that performs automatic syllabification and morpheme boundary segmentation called Balloon, a word classification system (Berkling and Reichel, 2014) that builds on Balloon output, and a syntactic parser (Petrov et al., 2006) followed by a sentence classifier.

4.1 Balloon and Lexical Analysis

The word counter uses the output of Balloon, which works roughly as follows, for details see (Reichel, 2012).

The Grapheme-phoneme (G2P) conversion is carried out by a C4.5 decision tree (Quinlan, 2003). Syllable boundaries are placed in front of each sonority minimum, and their locations are subsequently adjusted in case German syllable phonotactics is violated. Word stress is again assigned by a C4.5 tree that predicts for each syllable whether it is stressed or not. Part of speech (POS) labels were assigned by a Markov tagger that additionally makes use of information stored in word suffix strings. Relevant suffix strings are extracted by means of an adaptation of the peak and plateau algorithm of Nascimento (1998). As POS inventory the Stuttgart Tübingen tag set (Schiller et al., 1995) is used.

The morphological analysis yields a flat segmentation of a word into morphemes and their morpheme classes. Each word is therefore decomposed into phonemes, syllables, stress markers and morpheme boundaries that are then used by the morpheme and syllable counter. The word counter simply counts new and previously seen syllables and morphemes for each page and then plots new vs. previously seen numbers for each page. The word classifier uses syllable and morpheme boundaries to filter out the 2-syllable words that match the Trochee types and their 1-syllable derivatives as described in Section 2 by their unique identifying features in a rule based system.

4.2 Sentence Classifier

The sentence classifier takes its input from the Berkley’s parser for German, with -tokenize (to use the integrated tokenizer) and -accurate (favours accuracy over speed) options. A small set of simple rules - including ones designed to overcome some mistakes made by the parser - is used to assign levels according to Section 3.3 in decreasing order:

- looking for subordinate or coordinate clauses; this information is generally provided by the Berkley’s parser. However, to increase recall (some of these clauses where not tagged as such by the parser), it has here been reinforced by an upper layer using a list of words introducing subordinate clauses (dass, ob, ...) or coordinate clauses (und, oder, ...) and looking for verbs positions around these specific words in order to make the distinction between "Ich habe einen Bruder und eine Schwester." ("I have a brother and a sister.") and "Ich spiele und ich arbeite." ("I play and I work.").

- looking for auxiliary in 2nd position and past participle or infinite verb at the end of the sentence for level 4. Or finite verb in second position and particle at the end of the sentence.

- number of words and their part of speech for levels 1 and 2.

5 Data

Various primary texts were transferred into electronic format up to page 50. The primers were chosen for their popularity and opposing methodologies ranging from no apparent methodology towards syllable, grapheme, and whole word approach. The two old primers from 1877 and 1904
have been analyzed only in part. Their makeup is different from today’s primers. Separate sections are devoted to grapheme introduction, word-level training and sentence level training within progressively complex texts (as measured by sentence and word structure complexity). These sections have been extracted to demonstrate progression. Table 1 lists the available data.

6 Evaluation

Due to limited space, only the results for selected readers are displayed where they show prominent differences. Results are reported for morpheme and syllable repetition, progression of Trochee types, and sentence complexities.

6.1 Ability to Practice on Words and Syllables

Figures 3 and 4 show how many words or syllables are repeated or new for each page. There is quite a large difference in training when comparing Primers F & A with E & G, where there is substantially less repetition.

6.2 Progression towards Complexity at word level

The three diagrams in Figures 5 and 6 (See Appendix) show three different versions of progression for the different Trochee types and their 1-syllable derivatives. The figures are generated by looking at the distribution across the word types for every 5 consecutive words. Each slice on the x-axis therefore represents five words. The y-axis counts the number of word types for that slice from 1-5.

6.3 Progression at the Sentence Level

As depicted in the Appendix, Figures 7 to 9 show the progression in sentence complexity throughout the primers for three different books. Figure 7 depicts Primer F and some progression in the sentence structure can be seen throughout the reader. At the beginning of the book, there are lots of simple utterances (mainly Level 1, so Noun or Article+Noun), no Level 5 sentences (subordinate and coordinate clauses) and a few Level 3 sentences. As we proceed, we can observe more and more Level 3 sentences and the appearance of Level 4 sentences (verb tricks), while the number of Level 1 sentences decreases significantly. At the end of the book, there are lots of Level 4 and 5 sentences and almost no simple ones.

In contrast, Figure 8 depicts Primer E with no progression at all in the sentences structure. All the levels are merged all along the book, meaning children learn a few words and directly use them in complex sentences. Level 3 is the highest level of complexity reached, significantly diminishing the syntactic exercices that more complex sentences offer.

Figure 9 shows Primer from 1904 depicting the
progression taken from the special section on practicing sentence complexity. This progression is visible in the diagram. At the beginning of the analyzed part of the book, it can be observed that most of the sentences belong to Level 3. Then their number is slightly decreasing as we browse to the end of the book. Meanwhile there are an increasing number of Level 4 and 5 sentences. The number of high complexity sentences is significantly larger here than observed in contemporary primers.

7 Conclusion

Looking at primers through a quantitative lens revealed large differences in primary reading material for first graders who are introduced to reading with these materials. It is important to be aware of such differences that may not be apparent immediately. Today, these effects are not studied in quantitative, systematic manner and teachers are not aware of the detailed particularities of their materials. Obviously, these primers are only one component of many materials chosen by teachers to work with the children in training their reading and writing skills. This type of analysis covers only one aspect of the classroom dynamics. However, it would be desirable to see a clear progression in the examined material and an explicit goal of the skills that the students in first grade should be able to reach along with a defined progression in that direction. Based on our work, there is no evident answer as to which methodology has a clearer progression at different levels. None of the contemporary primers show the distinctive marks of the two chosen older versions that contain an apparent progression at the word and the sentence level that takes the elementary student from the simple to the complex. Looking at the older primers, much more complexity was demanded from first graders at the end of the school year. It may be that in order to reach that level more practice opportunities were supplied and explicit progression at various levels was needed.

Future work will have to study whether there is a cause and effect here. The old approach provides a stark contrast to our primers in use today and today’s primers differ significantly even among each other regarding practice and progression. None of the modern readers seem to spend the time (when compared to the older primers) on the typical German word structure of the Trochee. This work has shown that there are differences between readers, some of which are not well studied, and that there is a need to study the consequences this material has on student’s learning and achievements.
