Abstract

A study exploring the chemical behavior of some dihydroxylated β-amino ester stereo- and regioisomers, derived from unsaturated cyclic β-amino acids is described. The nucleophilic fluorinations involving hydroxy–fluorine exchange of some highly functionalized alicyclic diol derivatives have been carried out in view of selective fluorination, investigating substrate dependence, neighboring group assistance and chemodifferentiation.

Introduction

Fluorinated molecules exert an ever-increasing impact in medicinal chemistry thanks to their valuable biological properties. Numerous drugs introduced to the market nowadays contain fluorine, and their number is expected to continuously increase in years to come [1,2]. Therefore, there is a high demand in synthetic organic and medicinal chemistry for both, the synthesis of novel fluorinated biomolecules and the development of selective and controlled efficient fluorination procedures. This high interest is clearly demonstrated by the number of various published papers on the field, and related recent comprehensive reviews [3-12]. The nucleophilic fluorination with commercially available organic fluorinating agents (e.g., DAST, Deoxofluor, Fluolead, XtalFluor-E or XtalFluor-M) is a widely used approach for the introduction of a fluorine atom into an organic molecule. The most common approach is the exchange of a hydroxy group for fluorine, taking place, in general, by inver-

sion [13-18]. Although fluorination based on hydroxy–fluorine interconversion seems to be an eloquent, simple and efficient procedure for the creation of a certain fluorinated organic molecule, regio- and stereoselectivity, stereocontrol and substrate influence remain a challenge in the case of highly functionalized frameworks.

Results and Discussion

Our aim in this study was to explore the chemical behavior of some alicyclic, highly functionalized vicinal diol derivatives (accordingly possessing two fluorine precursor moieties in their structures) under fluorination protocols. During the past two decades multifunctionalized amino acids and their analogous derivatives have gained considerable interest in pharmaceutical chemistry as bioactive compounds. Some derivatives (e.g., peramivir, oseltamivir or laninamivir) are known as antiviral drugs [19-22], while other cyclopentane β-amino acids (e.g., icofungipen, cispentacin) are relevant antifungal agents [19]. Therefore we have selected some five and six-membered alicyclic dihydroxylated β-amino ester stereo- and regioisomers as model compounds [23-26], derived from cyclopentene or cyclohexene β-amino acids. These were used in order to evaluate their behavior in fluorination in view of selectivity and to explore substrate dependency and chemodifferentiation. Based on the different stereochemical structures of the selected model diols as well as the nature of the N-protecting group used, we expected differences in their chemical behavior under fluorination conditions. In a former investigation on oxirane opening reactions of various epoxycycloalkane β-aminocarboxylates [27], a high substrate dependence and directing effect of the functional groups has been observed. These results led us to perform similar investigations with the above mentioned dihydroxylated cyclic β-amino acid esters.

Our study started with the fluorination of racemic dihydroxylated cyclopentane cis- or trans-β-amino acid esters (±)-1 and (±)-4 [23-26]. The preliminary investigations were performed with the commercially available fluorinating agents mentioned above in various solvents (e.g., PhMe, THF, and CH$_2$Cl$_2$) at different temperatures. Hereby Deoxofluor in CH$_2$Cl$_2$ with or without adding DBU was found to be the most suitable reagent. The diol derivatives, obviously, are expected to deliver the corresponding difluorinated products. In spite of this anticipation, the treatment of dihydroxylated amino acid ester (±)-1 with 1.5 equiv of Deoxofluor after 70 min afforded through intramolecular cyclization a compound which was identified on the basis of 2D NMR analysis as oxazoline derivative (±)-2 as the sole product in 71% yield. When the same reaction was carried out in the presence of 4 equiv DBU as the base [28] the reaction time could be decreased to 10 min with a slightly increased yield of the product (Scheme 1). This observation led us to conclude that out of the two hydroxy groups only that attached to C-3 takes part in the reaction and is substituted via the amide O-atom. Increasing the amount of Deoxofluor to 4 equiv resulted in the exclusive formation of the fluorine-containing oxazoline derivative (±)-3. Note that the addition of DBU did not have a significant effect on this reaction. When isolated hydroxyoxazoline (±)-2 is subjected to the fluorination protocol compound (±)-3 was obtained in a modest yield (15%) that could be slightly increased to 25% by the addition of DBU to the reaction mixture (Scheme 1).

In contrast to (±)-1, its stereoisomer (±)-4, afforded in the reaction with 1.5 equiv of Deoxofluor in the presence of 4 equiv of DBU, according to 2D NMR and X-ray data fluoroxydrine derivative (±)-5 through chemodifferentiation in a moderate yield (Scheme 2, Figure 1).
This result indicated that in the case of compound (±)-4, the C-4 hydroxy group is transformed into a leaving group on interaction with Deoxofluor, followed by a fluoride attack to give (±)-5. Of note, the role of DBU was found to be crucial in this reaction, since without the addition of the base the formation of sulfite derivative T4 was detected (Scheme 2).

The vicinal fluorohydrine moiety is a relevant unit in a series of valuable biomolecules such as amino acids, heterocyclic natural products and nucleosides [29-36]. Therefore, the fluorinated β-amino acid derivative (±)-5, obtained through transformation of (±)-4 with chemodiscrimination of the alcoholic groups, might represent a promising bioactive framework.

As the fluorination of the five-membered diol stereoisomers (±)-1 and (±)-4 proved to be highly substrate dependent and on the basis of our earlier findings on substrate determinant fluorinations [37], we next investigated the effect of the nature of the N-protecting group on this reaction. The treatment of N-Cbz-protected dihydroxylated cyclopentane β-amino ester (±)-6 with Deoxofluor under various conditions provided an unidentifiable mixture of products. However, the reaction of diol (±)-6 with 1.5 equiv of Deoxofluor in the presence of DBU as the base furnished aziridine derivative (±)-7 within 10 min through intramolecular cyclization via the carbamate N-atom (Scheme 3). Again, only the selective transformation of the C-3 hydroxy group with the fluorinating agent took place, without the involvement of the C-4 OH group. Unfortunately, all further attempted fluorinations of hydroxylated aziridine (±)-7 under various conditions using for example XtalFluor, Et₃N·HF, and pyridine·HF and applying an efficient approach earlier developed by our group, proved to be unsuccessful ([18] and references cited therein).

Due to the biological relevance of six-membered β-amino acid derivatives (e.g., tilidin, oryzoxymicin, BAY99379) [19], we continued our synthetic investigations by selecting some cyclohexane β-amino acid esters as model compounds. Thus, diol (±)-8 [23-26] derived from dihydroxylation of cis-2-amino-cyclohex-4-ene carboxylic acid was treated with 1 equiv of Deoxofluor in CH₂Cl₂. Again, through chemodiscrimination of the alcoholic groups in positions 4 and 5, oxazine derivative (±)-9 was formed as the single product through intramolecular cyclization involving the nucleophilic amide O-atom (Scheme 4).

Upon treatment of diol (±)-8 with excess Deoxofluor (4 equiv), in addition to the expected fluorinated oxazine (±)-10, a highly unsaturated amino ester (±)-11 was formed as the major product. The two compounds were separated by column chromatography and product (±)-11 was identified to be a cyclohexadiene amino acid ester. A relatively simple way of its formation is depicted in Scheme 5. Specifically, after transformation of the
alcoholic group at C-4 in (±)-8 into a leaving group, an intramolecular cyclization takes place to afford oxazine (±)-9. Subsequently, this oxazine, in the presence of an excess Deoxofluor gives fluorinated derivative (±)-10. Finally, in the presence of fluoride as base, deprotonation (T9), followed by oxazine-ring opening through olefinic-bond migration (T10) then gives the highly conjugated amino acid ester (±)-11 (Scheme 5).

Noteworthy, the presence of DBU in the experiment of (±)-8 with Deoxofluor did not have a significant effect on the ratio of
the products. However, in the presence of the base the yields of 
(+)-10 and (+)-11 decreased to 10% and 17%, respectively.

Unfortunately and surprisingly, diol (+)-12 (derived from trans-
2-aminocyclohex-4-ene carboxylic acid) [23-26] a stereoisomer 
of (+)-8, in the reaction with either 1 equiv or excess of Deoxo-
fluor did not give any identifiable product. However, according to 
earlier observations on the effect of DBU the reaction in the 
presence of this base afforded keto ester (+)-13 in 41% yield. In 
contrast to the stereoisomer (+)-8, reaction of diol (+)-12 with 
Deoxofluor took place at the C-5 hydroxy group leading to 
intermediate T11. The latter, in the presence of DBU, gave enol 
T12 which immediately converted to keto amino ester (+)-13 
(Scheme 6).

Subsequently, we investigated the behavior of other six-mem-
bered diol isomers in this reaction. The diol derivative (+)-14 
(derived from cis-2-aminocyclohex-3-ene carboxylic acid), 
underwent intramolecular cyclization upon treatment with 
1 equiv of Deoxofluor providing isomers (+)-15 and (+)-16 in 
nearly 2:1 ratio that could be separated and isolated by chroma-
tography. This experimental observation indicates that in the 
case of diol (+)-14 both alcoholic groups are transformed into 
the corresponding good leaving groups upon treatment with De-
oxofluor. When (+)-14 was treated with an excess of Deoxo-
fluor, somewhat surprisingly, the fluorinated isoxazoline deriva-
tive (+)-17 was formed with the fluoride attached to the β-posi-
tion relative to the ester function, whereas the N-atom is locat-
ed in the γ-position through a β to γ flip (Scheme 7).

The formation of isoxazolines (+)-15 and (+)-16 in the pres-
ence of 1 equiv of Deoxofluor involves rather simple reaction 
steps as only one of the hydroxy groups is transformed into a 
leaving group in each case (T13 and T14, respectively). In 
contrast, when using the fluorinating reagent in excess, both 
hydroxy groups are converted to leaving groups to afford inter-
mediate T15. The latter affords aziridinium ion T16 through 
intramolecular reaction with the amide nitrogen. The subse-
quency azidine-ring opening by reaction with fluoride results in amide intermediate T17 which undergoes an intramolecular cyclization to give (+)-17 (Scheme 8). A similar aziridinium 
opening reaction with fluoride can be found in [38,39].

Interestingly, when changing the N-protecting group from 
benzoyl in (+)-14 to Cbz ((±)-18), the fluorination with Deoxo-
fluor provided, analogously to the five-membered compound 
(+)-6 (Scheme 3), aziridine (+)-19 in 60% yield (Scheme 9).

Diol (+)-20 (derived from trans-2-aminocyclohex-3-ene 
carboxylic acid), a stereoisomer of (+)-14, furnished selectively 
one single cyclized product in the presence of 1 equiv of De-
oxofluor, namely oxazoline derivative (+)-21 (Scheme 10). This 
is in high contrast to the transformation of (+)-14 (Scheme 7).

Interestingly, when (+)-20 is treated with Deoxofluor in excess, 
again, differently from its all-cis counterpart (+)-14, two fluori-
nated oxazolines in nearly 1:1 ratio are obtained: (+)-22 as the 
expected product, with the ring N-atom in the β-position to the 
ester group and compound (+)-23, having the N-atom in the
Finally, the fluorination protocol was applied to commercially available meso-compound 24 having a cyclohexane framework. However, the treatment of 24 with various amounts of Deoxofluor gave only unidentifiable products whereas the reaction in the presence of DBU, afforded ketoester (±)-25 (see also Scheme 6) in 48% yield (Scheme 11).

**Conclusion**

In conclusion, the chemical behavior of the alcoholic functions of some vicinal diol derivatives towards fluorination has been investigated under various conditions. The fluorination reactions of the highly functionalized cycloalkanes were found to be highly substrate dependent, taking place with chemodiscrimina-
tion of the two hydroxy groups. The stereochemical arrangement of the functional groups deeply influenced the selectivity of the transformations. Further investigations of other substrates in view of selectivity and substrate-directing effects are currently being studied in our research group.

**Experimental**

**General information**

Chemicals were purchased from Sigma–Aldrich and the solvents were used as received. Melting points were determined with a Kofler apparatus. Elemental analyses were carried out with a Perkin–Elmer CHNS-2400 Ser II elemental analyzer. Silica gel 60 F254 was purchased from Merck. The NMR spectra were acquired at room temperature on a Bruker Avance 400 spectrometer with 11.75 T magnetic field strength ($^1$H frequency: 400.13 MHz, $^{19}$F frequency: 376.50 MHz, $^{13}$C frequency: 100.76 MHz, respectively) in CDCl$_3$ or DMSO-$d_6$ solution, using the deuterium signal of the solvent to lock the field. The $^1$H and $^{13}$C chemical shifts are given relative to TMS and $^{19}$F chemical shifts are referenced to CFCl$_3$ (0.00 ppm).

**Method A:** To a solution of dihydroxylated compound (0.50 mmol) in 10 mL anhydrous CH$_2$Cl$_2$ under an Ar atmosphere, 4 equiv DBU and 1.5 equiv Deoxofluor in toluene was added (amount given in the text) and the reaction mixture was stirred at 20 °C for the time given in the text. The solution was then diluted with CH$_2$Cl$_2$ (30 mL) and washed with saturated aqueous NaHCO$_3$ (2 × 20 mL). The organic layer was dried (Na$_2$SO$_4$) and concentrated. The crude product was purified by column chromatography on silica gel ($n$-hexane/EtOAc or $n$-hexane/acetone).

**Method B:** To a solution of dihydroxylated compound (0.50 mmol) in 15 mL anhydrous CH$_2$Cl$_2$ under an Ar atmosphere, 4 equiv DBU and 1.5 equiv 50% Deoxofluor in toluene were added and the solution was stirred at 20 °C for the time given in the text. The solution was then diluted with CH$_2$Cl$_2$ (30 mL) and washed with saturated aqueous NaHCO$_3$ solution (2 × 20 mL). The organic layer was dried (Na$_2$SO$_4$) and concentrated. The crude product was purified by column chromatography on silica gel ($n$-hexane/EtOAc or $n$-hexane/acetone).
