44 ABSTRACT

45 The Nimrod gene cluster, located on the second chromosome of *Drosophila melanogaster*, is the
46 largest syntenic unit of the *Drosophila* genome. Nimrod genes show blood cell specific
47 expression and code for phagocytosis receptors that play a major role in fruit fly innate immune
48 functions. We previously identified three homologous genes (*vajk-1*, *vajk-2* and *vajk-3*) located
49 within the Nimrod cluster, which are unrelated to the Nimrod genes, but are homologous to a
50 fourth gene (*vajk-4*) located outside the cluster. Here we show that, unlike the Nimrod candidates,
51 the Vajk proteins are expressed in cuticular structures of the late embryo and the late pupa,
52 indicating that they contribute to cuticular barrier functions.

53

54 *Keywords:* gene cluster, Nimrod, innate immunity, *Drosophila*, cuticle development, trachea

55

56 1. Introduction

57 The protection of organisms from pathogens requires the concerted action of several layers of
58 defense, including mechanical and immune components. The first line of defense against
59 infection comprises a physical barrier, the skin, the mucosa and chemical barriers that stop
60 microbes and parasites from entering the body. If the pathogens are able to get past the physical
61 barrier, a constitutive second line of defense attacks the pathogens, which involves proteolytic
62 cascades in the body fluid, as well as phagocytosis mediated by a group of immune system cells.

63 The third line of defense is comprised of inducible antimicrobial peptides and effector cells,
64 differentiating after immune induction, involved in separation of large particles. These three
65 layers of defense are the major components of the innate immune system, a phylogenetically
66 conserved module, based on the same principles in all multicellular organisms, including insects
67 and mammals.

68 The Nimrod gene cluster, on the *Drosophila melanogaster* second chromosome, is a major
69 component of the innate immune response (Kurucz et al., 2007; Kurant et al., 2008; Zsámboki et
70 al., 2013). The distribution of genes in this cluster is similar over distantly related arthropod
71 species, indicating that the cluster remained predominantly intact during the last 300-350 million
72 years (Somogyi et al., 2010). The expression pattern of several genes located here is blood cell
73 specific, and the encoded proteins play a central role in the immune response. All Nim proteins
74 contain a characteristic EGF-repeat, the Nim-domain (Kurucz et al., 2007; Somogyi et al., 2008).
75 NimA, NimB1, NimB2 and NimC1 proteins possess bacterial binding capacity and are important
76 for the phagocytosis of bacteria (Kurucz et al., 2007; Zsámboki et al., 2013), the NimC4 (SIMU)
77 protein has role in glial phagocytosis of apoptotic neurons (Elliott and Ravichandran 2008;
78 Kurant et al., 2008; Shklyar et al., 2013). Another Nim family member, Hemese, was shown to
79 play a modulatory role in hemocyte activation or recruitment (Kurucz et al., 2003).

80 Besides the *Hemese* and *Nim* genes, the cluster also contains candidates with yet unknown
81 function. The *vajk-1*, *vajk-2* and *vajk-3* genes are located in the large intron of *ance-3*, and are
82 transcribed in the opposite direction. The *ance* genes were suggested to be involved in immune
83 defense, as in *Locusta migratoria* hemocytes, their expression is significantly enhanced after
84 stimulation by bacterial lipopolysaccharides (Macours et al., 2003; Duressa et al., 2016) or
85 following a *Wolbachia* infection in the fruitfly (Xi et al., 2008). The *vajk-4* gene, a paralogue of
86 the *vajk-1*, *vajk-2* and *vajk-3* genes, is located outside of the cluster, but still on the second
87 chromosome. The *vajk* genes were previously suggested to play roles in the innate immune
88 defense (Irving et al., 2005; Somogyi et al., 2010). We have therefore carried out a molecular and
89 immunological analysis of the encoded proteins and reveal that they exhibit characteristics of
90 cuticular proteins and therefore are essential components of the cuticle, the mechanical barrier
91 facing the challenges by pathogen.

92

93 **2. Materials and methods**

94

95 *2.1. Drosophila stocks and culturing*

96

97 The following fruit fly stocks were used: wild type *Oregon R*, *w¹¹¹⁸*, *w;actin-GAL4/CyO,GFP*
98 (4414), *w;Da-GAL4* (55849), *w; alphaTub67C-GAL4* (7063), *w;UAS-GFP* (4775) from
99 Bloomington Drosophila Stock Center, *l(3)mbn-1/TM6B, Tb* (Konrad et al., 1994), *w;btl-GAL4*
100 (Shiga et al., 1996), *Flip-FRTy,w,UAS-FLP;Act5C-FRT-STOP-FRT-GAL4,UAS-GFP* lineage
101 tracing line (Honti et al., 2010). *UAS-RNAi* transgenic stocks were obtained from the Vienna
102 *Drosophila* RNAi Center (<http://stockcenter.vdrc.at>) and from the National Institute of Genetics
103 RNAi Center (NIG-fly), Kyoto (www.shigen.nig.ac.jp/fly/nigfly/). For the analysis of the *vajk-1*
104 gene the V102445/KK, V38024, V38026 and 16886-R3 for the *vajk-4* gene the 36642 and the
105 15514 *UAS-RNAi* transgenic stocks were used. Strains were kept at 25°C on standard yeast-
106 cornmeal food. Age-synchronized *Drosophila* populations were used in the experiments. The
107 early pupae represents 1:1 mixture of 24 and 48 h, and the late pupae 1:1 mixture of 72 and 96 h
108 pupae harvested after puparium formation.

109

110 *2.2. Isolation of RNA and synthesis of the cDNA*

111

112 The RNA was isolated using TRIzol Reagent (Invitrogen). The contaminating DNA was
113 eliminated by DNase I treatment (Fermentas): 1 µg RNA was treated with 1 u DNase I and then
114 reverse transcribed using RevertAid First Strand cDNA Synthesis Kit (Fermentas).

115

116 *2.3. Reverse transcribed polymerase chain reaction (RT-PCR)*

117

118 In the RT-PCR 1 µl undiluted cDNA was used as template and 40 cycles were applied. The
119 primer sets used to detect the transcription of the *vajk* genes are listed in Table 1. The *vajk-1* fw
120 and *vajk-1* AB rev primers were used to amplify an 1031 bp fragment representing both, the
121 CG16886-RA and the CG16886-RB *vajk-1* transcripts; *vajk-2* fw and *vajk-2* rev were used for
122 detecting the *vajk-2* transcript (828 bp), *vajk-3* fw and *vajk-3* rev for the *vajk-3* transcript (849
123 bp) and *vajk-4* fw and *vajk-4* rev for the *vajk-4* transcript (1003 bp) respectively. To test the
124 quality of the cDNA isolated from blood cells we used the hemese fw and hemese rev primers,

125 which generate a 175 bp fragment. In case of genomic DNA contamination, a 354 bp PCR
126 fragment was expected. To analyze the performance of the *vajk* specific primer sets, we also used
127 vectors containing *vajk* cDNAs as templates in the PCR. The RH73259, RH04334, HL02234 and
128 LD27203 cDNA vectors, were obtained from BDGP Gold cDNA Collection
129 (<https://dgrc.cgb.indiana.edu/vectors/Gold>). Furthermore, in positive control reactions the
130 housekeeping ribosomal gene specific rp49 fw and rp49 rev primer set was used, which amplifies
131 a 316 bp fragment.

132

133 2.4. Generation of constructs encoding the recombinant *Vajk* proteins

134

135 To amplify the entire coding region of the *vajk* genes the RH73259 (*vajk-1*), the RH04334
136 (*vajk-2*), the HL02234 (*vajk-3*) and the LD27203 (*vajk-4*) cDNA clones were used as templates.
137 In case of the *vajk-1* gene we used the *vajk-1* fw and *vajk-1* A rev primers (Table 1), which
138 generate an 1137 bp fragment consisting the coding region of the CG16886-RA, without its stop
139 codon. For the *vajk-2*, *vajk-3* and the *vajk-4* genes we used the same primer set as in case of the
140 RT-PCR (Table1). Because the used primers carry adapter restriction sites the obtained fragments
141 were digested with EcoRI and XbaI restriction enzymes and cloned in the EcoRI/XbaI site of the
142 pB-FLAG vector (Zsámboki et al., 2013). The obtained pGC22, pGC16, pGC14 and pGC24
143 clones carry the *vajk-1*, the *vajk-2*, the *vajk-3* and the *vajk-4* cDNA fragments respectively,
144 followed in frame by the FLAG tag coding region, two stop codons and an additional NotI
145 restriction site. DNA sequence analysis was done using a BigDye Terminator v3.1 Cycle
146 Sequencing Kit (Invitrogen) and a 3500-Genetic Analyzer (Applied Biosystems). The obtained
147 plasmids were digested with EcoRI and NotI restriction enzymes and after isolation of the
148 fragments containing the whole fusion constructs, they were cloned in the EcoRI/NotI site of the
149 pENTR3C vector (Invitrogen). pGC44 (*vajk-1*), pGC38 (*vajk-2*), the pGC42 (*vajk-3*) and the
150 pGC46 (*vajk-4*) plasmids were obtained. With site-specific recombination using Gateway
151 reaction the fusion constructs were further transferred into the pDESTTM20 vector (Invitrogen).
152 The pDESTTM20 moreover provides a polyhedrin promoter and an N-terminal GST tag coding
153 region to the constructs. The obtained pGC63 (*vajk-1*), pGC66 (*vajk-2*), the pGC69 (*vajk-3*) and
154 the pGC72 (*vajk-4*) clones were used for transforming DH10Bac *E. coli* competent cells
155 (Invitrogen). The DH10Bac cells contain a baculovirus shuttle vector (bacmid) that can

156 recombine with the pDEST20. The recombinant clones carrying the constructs (polyhedrin
157 promoter, N-terminal GST tag, *vajk* coding region, C-terminal FLAG tag, stop codons), were
158 selected according to the manufacturer's instructions.

159 To create the plasmid construct expressing the Vajk-FLAG recombinant proteins, the
160 previously described EcoRI/NotI fragment carrying the *vajk* cDNA fragment and the FLAG-tag
161 coding regions, were cloned into the EcoRI/NotI site of pFastBacTMDual vector (Invitrogen),
162 downstream of the polyhedrin promoter. The obtained pGC51 (*vajk-1*), the pGC29 (*vajk-2*), the
163 pGC32 (*vajk-3*) and the pGC52 (*vajk-4*) clones were used to generate bacmid DNS construct as
164 described above.

165

166 2.5. Expression and isolation of the recombinant Vajk proteins

167

168 The recombinant Vajk proteins were expressed in a baculovirus expression system (Bac-to-
169 Bac, Invitrogen). The obtained bacmid DNA constructs, described above, were isolated and Sf9
170 cells were transfected using Cellfectin II reagent (Invitrogen). Sf9 cells were grown in TNM-FH
171 Insect Medium (Invitrogen) supplemented with 10% fetal calf serum (PAA Laboratories GmbH)
172 and 5mM glutamine (PAN Biotech). The transfected Sf9 cells produced the recombinant Vajk
173 proteins. For protein isolation the used lysis buffer contained 150 mM NaCl (Molar Chemicals
174 Kft), 40 mM Tris (Reanal) pH 7.5, 10% glycerol (Merck), 0.1 % NP40 (Fluka), 5 mM EDTA
175 (Sigma), 1mM PMSF (Sigma) and Complete Protease Inhibitor Cocktail (Roche) according to
176 the manufacturer's instructions. Sf9 cells (8×10^3) were suspended in 1 ml lysis buffer and were
177 three times sonicated for 1 min on ice, each sonication followed by freezing (in liquid nitrogen)
178 and thawing. The protein lysates were centrifuged at 18000xg for 10 min at 4°C. Supernatants
179 containing the GST-Vajk-FLAG recombinant proteins were incubated with Glutathione
180 Sepharose 4B (GE Healthcare) 4 h at 4°C. Beads were washed 3 times with high salt buffer (1M
181 NaCl, 40 mM Tris pH 7.5, 10% glycerol, 0.1 % NP40, 5 mM EDTA) and three times with low
182 salt buffer (150 mM NaCl, 40 mM Tris pH 7.5, 10% glycerol, 0.1 % NP40, 5 mM EDTA).
183 Elutions were done in low salt buffer containing 33mM glutathione, reduced (Reanal). Eluted
184 samples were boiled 5 min in sample buffer containing 0.6 M DTT (Thermo Scientific), loaded
185 for SDS-PAGE and analyzed with Western blot using monoclonal mouse anti-FLAG M2
186 antibody (Sigma) at a dilution of 1:1000. Samples were loaded for SDS-PAGE and stained with

187 Coomassie Brilliant Blue. Gels were destained with 10% acetic acid followed by washing 4 h in
188 sterile Millipore water. The respective protein bands were excised.

189

190 2.6. Immunization and analysis of antibody specificity

191

192 Gel sections containing the GST-Vajk-FLAG recombinant proteins were homogenized in
193 sterile PBS buffer, and 10 µg recombinant protein was injected in Complete Freund Adjuvant
194 (DIFCO) subcutaneously into BALB/c mice. Immunization was repeated monthly, to a total of
195 four times in Incomplete Freund Adjuvant (DIFCO). One week after the fourth immunization
196 antisera were prepared and tested using Western blot analysis on lysates of Sf9 cells, expressing
197 the recombinant Vajk-FLAG proteins. Monoclonal mouse anti-FLAG antibodies (Sigma) were
198 used as positive controls. In parallel the obtained antibodies were also tested on *Drosophila*
199 samples. Although each antibody displayed the expected signals on Sf9 lysates, the anti Vajk2
200 and the anti Vajk3 antibodies were unreactive on *Drosophila* samples (data not shown).

201

202 2.7. Indirect immunofluorescence and immunohistochemistry

203

204 Localization of the Vajk proteins was analyzed with indirect immunofluorescence, as follows.
205 The chorion of the embryos was removed with 2 min incubation in 21 g/l sodium hypochloride.
206 Samples were washed with water extensively followed by vitelline membrane permeabilization
207 and fixation for 40 min in a 1:1 mixture of n-heptane (Reanal) and 35% formaldehyde (Reanal).
208 One volume of -20°C cold methanol was added to the samples and was shaken vigorously for one
209 min to remove the vitelline membrane. Liquid components of the sample were removed and
210 embryos were washed 3 times with cold methanol, followed by washing for 5 min in 2:1
211 methanol: PBT [PBS, 0.1% Triton X-100 (Sigma)]; 5 min in 1:1 methanol:PBT; two times 10 min
212 in PBT and once 30 min in BBT [PBS, 0.1% Triton X-100, 0.1% BSA (Sigma)]. Primary
213 antibodies were diluted 1:500 in PBT-N (PBT, 1% BSA, 5% fetal calf serum) and incubated with
214 the samples overnight at 4 °C. Mouse anti β-tubulin E7 (Hybridoma bank) monoclonal antibody
215 1:100, and normal mouse serum, 1:500 were used as controls. Washing was performed 3 times
216 for 5 min and once for 30 min in PBT. Alexa Fluor 488 goat anti mouse IgG (Invitrogen, 1:1000)
217 was used as secondary antibody and DAPI (Sigma 1:400) for visualization of the nuclei, both

218 diluted in BBT. Incubation was done for 1 h at room temperature, followed by three 10 min
219 washes in PBT. Samples were mounted in Fluoromount-G (SouthernBiotech). Cuticle
220 preparations were fixed with 2% paraformaldehyde for 10 minutes, and blocked with 0.1% BSA
221 in PBS supplemented with 0.01% Triton X-100 for 20 min. Following the incubation with the
222 primary antibodies (as described above) samples were washed 3 times for 5 min in PBS,
223 incubated with secondary antibodies for 45 min, washed 3 times for 5 min and mounted in
224 Fluoromount-G. Samples were examined with an epifluorescence microscope (Zeiss Axioskope 2
225 MOT) or an Olympus FV1000 confocal LSM microscope. Images were edited and analyzed with
226 the ImageJ program (<http://imagej.nih.gov/ij/>).

227 To analyze the tracheolae running along the indirect flight muscles of the *vajk-1* silenced
228 pupae, pharate adults were reared at 29°C and dissected from the pupal case at stage P15. After
229 removal of their head and the abdomen, the remaining thoraxes were fixed for 2 hours in PBS
230 with 4% formaldehyde. The thoraxes were then washed in PBS and soaked in PBS with 10%
231 sucrose over night at 4°C, before being embedded in OCT and cryosectioned into 6-10 µm slices.
232 The sections were labelled with anti-Nidogen (1:1000, kindly provided by Ruth Palmer, used
233 previously by Wolfstetter et al., 2009 and a FITC-conjugated chitin-binding probe (1:500, New
234 England Biolabs #P5211S) and viewed by confocal imaging.

235 For immunohistochemistry samples were fixed and incubated with the first antibody as
236 described for the indirect immunofluorescence. The primary antibody was detected with
237 Biotinylated Polyclonal Goat Anti-Mouse Immunoglobulin and Streptavidin/HRP (Dako
238 Denmark A/S). The chromogen was 3-amino 9-ethylcharbasole (Sigma).

239 240 2.8. Western blot analysis

241
242 Whole organisms of different developmental stages were used to prepare lysates for Western
243 blot analysis as described under section 2.5. The protein concentration of the samples was
244 determined and 300 µg protein was loaded in each well of the 10% SDS-PAGE. The sample
245 buffer contained DTT. Following the separation, proteins were transferred to a PVDF membrane
246 (Millipore) using a wet electroblotting system (Bio-Rad). The membranes were blocked for 1 h
247 with TBS buffer (10 mM Tris pH 7.5, 150 mM NaCl) containing 5% fat free milk powder, rinsed
248 with TBS and incubated with the primary antibodies diluted in TBS containing 1% BSA, for 1 h.

249 The membranes were washed 3 times with TBS, 10 min each, followed by incubation with
250 HRPO-anti-mouse IgG secondary antibodies (GE Healthcare) at a dilution of 1:5000. The
251 reaction was visualized with ECL Plus (GE Healthcare) according to the manufacturer's
252 instructions.

253

254 2.9. Chitin binding assay

255

256 Sf9 cells (8×10^3) producing Vajk1-FLAG, Vajk4-FLAG, and NimC1-FLAG (Zsámboki et al.,
257 2013) recombinant proteins were lysed in 1 ml lysis buffer containing 150 mM NaCl (Molar
258 Chemicals Kft), 40 mM Tris (Reanal) pH 7.5, 10% glycerol (Merck), 0.1 % NP40 (Fluka), 5 mM
259 EDTA (Sigma), 1mM PMSF (Sigma) and Complete Protease Inhibitor Cocktail (Roche),
260 according to the manufacturer's instructions. Each lysate was incubated for 2 h at 4°C with 40 µl
261 Anti-Flag (DYKDDDDK) Affinity Gel (biotool.com). The affinity gels were washed 5 times in
262 1500 µl TBS and the bound material was eluted two times with 100mM glycine HCl pH 2.5, 250
263 µl each. The obtained samples were dialyzed on a cellulose membrane (Sigma-Aldrich) against
264 chitin binding buffer (20mM Tris, 500mM NaCl, 0.05% Triton X-100 (Sigma), pH 7.5) overnight
265 at 4°C. Each protein solution was incubated with 200 µl chitin beads (New England Biolabs), 6 h
266 at 4°C, then the beads were washed 5 times with 1500 µl binding buffer. To elute chitin bound
267 protein, the washed chitin beads were incubated at 4°C for 10 min with 300 µl of 8M urea
268 (Sigma), twice. Fractions were pooled, precipitated with trichloroacetic acid (CARLO ERBA) and
269 washed two times with 1500 µl ice cold acetone. Precipitates were dissolved in DTT sample
270 buffer and analyzed by SDS-PAGE and Western blot.

271 2.10. Electron microscopy

272 Tissue samples were fixed overnight at 4°C in a pH 7.4 solution of 3.2%
273 paraformaldehyde, 0.5% glutaraldehyde, 1% sucrose, and 0.028% CaCl₂ in 0.1 N sodium
274 cacodylate. Postfixation was carried out in 0.5% osmium tetroxide for 1 h, followed by
275 embedding in Durcupan (Fluka) according to the manufacturer's recommendations. 90 nm
276 sections were made by Reichert Ultracut ultramicrotome and stained in Reynold's lead citrate.
277 Sections were viewed in a JEM-1011; JEOL transmission electron microscope, and pictures
278 taken with a Morada; Olympus camera and iTEM software (Olympus).

279

280 3. Results

281

282 3.1. Molecular characteristics of the Vajk proteins

283

284 The *D. melanogaster* *vajk-1*, *vajk-2*, *vajk-3* and *vajk-4* genes (*CG16886*, *CG16885*, *CG16884*
285 and *CG30101*) encode proteins with relatively small size (between 270 and 373 amino acids) and
286 similar sequence properties (Somogyi et al., 2010). The analysis of the Vajk1, Vajk2, Vajk3 and
287 Vajk4 protein sequences reveals several repetitive segments (Fig. 1A). The presence of the low
288 complexity regions and short repetitive sequences is particularly characteristic of cuticular
289 proteins (Cornman and Willis 2009, Mun et al., 2015). Comparison of the Vajk sequences using
290 the Kalign Multiple Sequence Alignment Tool (Lassmann and Sonnhammer, 2005),
291 (<http://www.ebi.ac.uk/Tools/msa/kalign/>), revealed 34% to 50% identity. Moreover, we identified
292 a consensus region in each Vajk protein, which also implies the presence of repetitive segments
293 (Fig. 1B). According to flybase, www.flybase.org, Vajk1 has two isoforms, of which Vajk1-PA is
294 15 amino acids longer at the C-terminal region than Vajk1-PB.

295 By using NCBI and UniProt BLAST the Vajk proteins were found to be 49 to 80% identical
296 to several cuticular proteins identified in other insect species, such as *Bombyx mori* (Ali et al.,
297 2015; Futahashi et al., 2008; Suetsugu et al., 2013), *Danaus plexippus* (Zhan et al., 2011),
298 *Operophtera brumata* (Derks et al., 2015), *Anopheles gambiae* (He et al., 2007), *Papilio polytes*
299 (Futahashi et al., 2012) and *Papilio xuthus* (Futahashi and Fujiwara, 2008; Futahashi et al., 2012).
300 The repetitive sequences found in the Vajk proteins (Fig. 1A) are present in these orthologs
301 (Table 2.). Moreover, the consensus sequence found in the *Drosophila* Vajk proteins (Fig.1B) is
302 also present in the orthologs (Fig. 1C).

303

304 3.2. Expression pattern of the vajk genes

305

306 As several Nimrod-cluster genes are expressed in hemocytes (Kurucz et al., 2003; Kurucz et
307 al., 2007; Kurant et al., 2008; Zsámbocki et al., 2013), we tested whether the *vajk* genes are also
308 transcribed in these cells. RT-PCR analysis of RNA from hemocytes of the homozygous *l(3)mbn-*
309 *1* mutant larvae, carrying all blood cell types, could not detect any of the *vajk* transcripts (Fig.

310 2A). Developmental analysis revealed that all four *vajk* transcripts are present in the embryo, in
311 the first and second larval stages, in pupae and in one-day-old adults (Fig. 2B). In third instar
312 larvae, low *vajk-2* and *vajk-3* mRNA levels were detected, while the *vajk-1* and *vajk-4* transcripts
313 were undetectable. Only the *vajk-4* gene was still expressed in 10-day-old adults.

314

315 3.3. *Vajk* protein localization

316

317 To analyze the expression pattern of the Vajk proteins, the generated anti-Vajk sera were
318 tested on Sf9 cells expressing the respective recombinant proteins, as well as on fly extracts
319 obtained from different developmental stages. Although all four antibodies reacted with the
320 corresponding Sf9 cells, antibodies to Vajk2 and Vajk3 did not react with fly extracts. For this
321 reason we carried out subsequent analysis with the Vajk1 and Vajk4 specific antibodies.

322 In 16-17 stage embryos the Vajk1 protein is expressed in the esophagus, the ducts of the
323 salivary glands, the trachea and the denticle belts of the ventral epidermis (Fig.3A). It is not
324 expressed in any larval stages but is present in late, 72 h old pupae (P9-P11 pupal stages).
325 Analysis of the late pupae (Fig. 4) for Vajk1 expression with indirect immunofluorescence
326 revealed staining of a branching structure, the developing trachea, on the surface of the indirect
327 flight muscles (Fig. 4A'). To confirm the tracheal expression we used the tracheoblast-specific
328 *btl-GAL4* driver in combination with *UAS-GFPn*. As the *btl* promoter exhibited low activity at 72
329 h after puparium formation (at which stage the Vajk1 protein signal was the most intense), we
330 applied lineage tracing (Ito et al., 1997; Honti et al., 2010) with the *btl-GAL4* driver. As shown in
331 Fig. 4A the expression of the Vajk1 protein overlapped with the lineage traced cells. Surface plot
332 analysis (Fig. 4C) of the images of the stained tracheoles revealed that the Vajk1 signal (far red)
333 intensity is higher at the region located between the high intensity GFP signals, indicating that the
334 Vajk1 protein is located inside the tracheolar tubes surrounded by tracheoblasts.

335 Indirect immunofluorescence analysis of the embryos for Vajk4 protein expression revealed
336 that it is present in the denticle belts of the ventral epidermis and trachea of 16-17 stage embryos
337 (Fig. 3B), similar to Vajk1. The protein was also detected in the epidermis of the 72 h old pupae,
338 expressed homogenously in the cytoplasm of the hair cells and showed a granular distribution in
339 the rest of the epidermal cells (Fig. 5A).

340 Western blot analysis of Vajk1 showed that both isoforms (41 and 43 kDa) were present in
341 late embryos and in 72 h old pupae (P9-P11 pupal stages) (Fig. 6) in agreement with the indirect
342 immunofluorescent data. The Vajk4 signal (38.1 kDa) was detected in the embryo, in the pupa and
343 the adult (Fig. 6). Neither protein was detected in larvae (Fig. 6).

344

345 *3.4. Silencing the vajk-1 and the vajk-4 genes with RNA interference*

346

347 To silence the *vajk* genes, *UAS-vajk-RNAi* constructs and the ubiquitous *Da-GAL4* driver
348 were used. For embryonic gene silencing the *alphaTub67C-GAL4* driver was applied, which
349 possesses exclusive maternal expression.

350 The *vajk-1* gene was silenced by crossing the V102445/KK, V38024, V38026 and 16886-R3
351 lines to the ubiquitous driver at 29°C. The F1 generations exhibited a pupal lethal phenotype.
352 When using the V102445/KK line lethality did not appear until the late pupal stage, hence we
353 used this line to study Vajk1 protein levels in 72 h old pupae after RNA silencing. For this
354 purpose we used *102445/KK/UAS-GFP;Da-GAL4/+* flies, where the GFP marker helped with
355 accurate selection of the live pupae at 72 h of pupal development. We tested the presence of the
356 Vajk1 protein using immunohistochemical staining and Western blot analysis in the *vajk-1*
357 silenced flies. The protein was not detected in the trachea (Fig. 4D). The Western blot analysis
358 confirmed this finding, as the Vajk1 protein was absent in lysates obtained from 72 h old pupae
359 (Fig. 4E).

360 The *vajk-4* gene was silenced using the 15514 and the 3642 *UAS-RNAi* transgenic stocks. As
361 revealed by indirect immunofluorescence (Fig. 5B) and Western-blot analysis (Fig. 5C), silencing
362 with the *Da-GAL4* driver resulted in strong decrease of the Vajk4 signal in the epidermal cells of
363 the 72 h old pupae, yet no visible phenotypic changes were observed in the pupae or adults.

364 Following gene silencing, both proteins showed decreased levels in the late embryos in
365 immunofluorescence and Western blot analysis, however no phenotypic changes were observed
366 (data not shown).

367

368 *3.5. Vajk1 and Vajk4 proteins bind to chitin and absence of the Vajk1 causes remarkable changes* 369 *in the structure of the cuticle*

370

371 The insect cuticle is composed of two main layers, the epicuticle and the procuticle, providing
372 a mechanical barrier and ensuring strength, as well as protecting the organism from dehydration
373 and infection. The epicuticle, built up of lipids and fibrous proteins, is the thin upper layer,
374 constituting the envelope of the cuticle. The procuticle is the thick inner layer, which is mainly
375 composed of chitin and proteins. Chitin is a polymer of N-acetylglucosamine monomers and is
376 embedded in a protein mesh. Several cuticular proteins have been shown to bind to chitin (Rebes
377 and Willis, 2001; Dong et al., 2016). We analyzed whether the *D. melanogaster* Vajk1 and Vajk4
378 proteins also have chitin binding capacity. Vajk1-FLAG and Vajk4-FLAG recombinant proteins
379 were produced in Sf9 cells and isolated by Anti-FLAG affinity gel, before being used in chitin
380 binding assays. As a negative control we used NimC1-FLAG recombinant protein (Zsámboki et
381 al., 2013). Samples were analyzed by SDS-PAGE and Western blot, using monoclonal mouse
382 anti-FLAG antibodies. As shown in Fig. 7A the Vajk1 and Vajk4 proteins bind to chitin.

383 The cuticle also forms the internal lining of the tracheal tubes. The structure of this cuticle is
384 different from the epidermal cuticle due to the presence of the taenidial folds, forming a helical
385 structure protruding into the lumen, providing stability and flexibility to the respiratory tubes.
386 The taenidial folds include taenidia, which provide them reinforcement (Matusek et al., 2006;
387 Öztürk-Colak et al., 2016). As the Vajk1 protein was shown to be present in the tracheolae
388 running along the indirect flight muscle, we analyzed the structure of these tracheolae in *vajk-1*
389 silenced pupae. A FITC-conjugated chitin-binding probe and an anti-Nidogen antibody were used
390 on cross sections of the indirect flight muscles in P15 stage pupae to visualize the chitin and the
391 basement membrane respectively in indirect immunofluorescence. A striking reduction was
392 revealed in chitin-marked tracheoles innervating the muscles of the *vajk-1* silenced samples,
393 compared to the parental strains (Fig. 7 B). Moreover electron microscopy pictures reveal
394 remarkable differences in the appearance of the cuticle in Vajk1 silenced specimens (Fig. 7C). In
395 the electron microscopy sections both parental control phenotypes are characterized by a strictly
396 regular cuticular lining with an evenly spaced wave-like appearance of the epicuticular layer; the
397 basal procuticular surface on the other hand is only very slightly wavy. As a result of this
398 arrangement the thickness of the procuticle gets increased right under the crest of the wave, in
399 addition, a taenidium can be observed in each of these taenidial folds (thicker regions). In the
400 *vajk-1* silenced samples each cuticular layer follows the wavy course, the waves are less regular,
401 the thickening of the procuticle and the taenidium is practically missing.

402

403 **4. Discussion**

404

405 We previously described that several Nimrod cluster genes encode proteins with roles in the
406 innate immune responses of *D. melanogaster* (Kurucz et al., 2003; Kurucz et al., 2007; Zsámboki
407 et al., 2013). As the cluster has been present in arthropod genomes for more than 300 million
408 years (Somogyi et al., 2008; Somogyi et al., 2010) it is possible that the genes located in this
409 cluster might be involved in a common biological process (Hurst et al., 2004; Lee and
410 Sonnhammer, 2003), therefore we analyzed new candidates of the cluster, the *vajk* genes. We
411 found that unlike the previously analyzed *nim* and *Hemese*, the *vajk* genes are not transcribed in
412 hemocytes. Previously, it was shown that each Vajk protein contains an N-terminal signal
413 peptide, suggesting that they are secreted and possess extracellular function. Their amino acid
414 sequences contain about 20% valine, being the most abundant amino acid (Somogyi et al., 2010).
415 Moreover here we found that they are homologous with other proteins described to be cuticle
416 components. It is known that the insect cuticle, composed primarily of low complexity proteins
417 (Cornman and Willis, 2009) and the polysaccharide chitin, represents the first barrier against
418 invading microorganisms; meanwhile, it also protects the organism from environmental damage
419 and dehydration (Tzou et al., 2000; Vincent and Wegst, 2004).

420 The cuticle of *D. melanogaster* is first produced during embryonic developmental stage 16
421 (Ostrowski et al., 2002), and it is present not only on the body surface, but also forms the internal
422 lining of the tracheae, the salivary ducts and the gut (Moussian et al., 2006). We detected the
423 presence of the Vajk1 protein in all these structures in late (16, 17) embryonic stages (Fig.3A).
424 The Vajk4 protein showed a similar expression profile to Vajk1 (Fig.3B). It was observed in the
425 denticle belt areas and in the trachea, but it could not be detected in the esophagus or the ducts of
426 the salivary glands, where the Vajk1 was also expressed. The *vajk-4* (CG30101) RNA *in situ*
427 hybridization data (available in the BDGP database) reveals RNA expression in the denticle belt
428 and the trachea of embryos in 13-16 developmental stages ([http://insitu.fruitfly.org/cgi-
429 bin/ex/report.pl?ftype=1&ftext=CG30101](http://insitu.fruitfly.org/cgi-bin/ex/report.pl?ftype=1&ftext=CG30101)), where in the later stages we detected the presence of
430 the Vajk4 protein. Our Western blot data also supports the presence of the Vajk1 and Vajk4
431 proteins in the late embryonic developmental stages (Fig.6). Moreover, the BDGP and Fly-FISH
432 databases also contain embryonic RNA *in situ* hybridization data on the *vajk-2* (CG16885)

433 (<http://insitu.fruitfly.org/cgi-bin/ex/report.pl?ftype=1&ftext=CG16885>) and the *vajk-3*
434 (CG16884) (<http://insitu.fruitfly.org/cgi-bin/ex/report.pl?ftype=1&ftext=CG16884>). Signals can
435 be observed in the denticle belts and the trachea, which suggests that the expression pattern of the
436 *vajk* genes overlaps in these tissues.

437 Following embryogenesis, cuticle differentiation involves complete renewal during larval and
438 pupal stages (Truman and Riddiford, 1999). The cuticular proteins are generally secreted by the
439 epidermal epithelium (Ostrowski et al., 2002), but in the tracheae and tracheoles several cuticular
440 proteins were shown to be transported through the epithelial cells from the hemolymph (Sass et
441 al., 1994; Dong et al., 2014). We observed the presence of the Vajk1 in the 72 h old pupae in
442 tracheoles connected to the developing indirect flight muscles. The tracheoles invading the
443 indirect flight muscles of the pharate adult develop from the dorsal air sac already present in the
444 third instar larvae (Cabernard et al., 2004). According to the literature, the indirect flight muscle
445 invasion ends after the terminal branches enter the T-tubules, extending within the myocyte and
446 encircling the mitochondria of the flight muscle. This process is completed at 70 h after puparium
447 formation (Peterson and Krasnow, 2014), at which point the Vajk1 protein appears in the
448 cuticular layer of the tracheoles. With indirect immunofluorescence the protein can be detected in
449 96 h old pupae, but the signal is weaker compared to that observed in 72 h old pupae, which may
450 be the consequence of the conformational changes in the protein as a result of cuticle
451 sclerotization, leading to the masking of the active epitopes for the antibody (Locke et al., 1994).
452 We could not detect the presence of the Vajk1 protein with Western blot in 96 h old pupae, which
453 may be due to the sclerotization that probably blocks the possibility for the Vajk1 to enter the
454 protein lysates used for the Western blot. To increase the protein isolation efficiency, beside the
455 homogenization of the pupae we also applied sonication of the samples but the Vajk1 protein
456 could still not be detected in the protein lysates.

457 Vajk4 protein, similar to Vajk1, is not expressed in the third instar larva, and shows the
458 highest expression level in 72 h old pupae, where indirect immunofluorescent analysis revealed
459 its presence in the epithelial cells of the body surface. Although Western blot analysis still shows
460 the presence of the protein in 96 h old pupae and in the adult, at these stages we could not detect
461 the protein in the epithelial cells with indirect immunofluorescence.

462 Several Vajk protein orthologs are considered to be cuticular proteins of different insect
463 species. Three Vajk orthologs of *Anopheles gambiae* (Fig. 1, Table 2) were isolated from cast

464 cuticles (He et al., 2007). Moreover it was formally shown that two Vajk orthologs, CPG12 and
465 CPG13 from *Bombyx mori*, bound chitin (Dong et al., 2016). Using chitin binding assays, we
466 show that the *D. melanogaster* Vajk1 and Vajk4 proteins also bind chitin (Fig. 7A). Furthermore
467 immunofluorescence experiments revealed a striking reduction in chitin marked tracheoles
468 innervating the indirect flight muscles of the *vajk-1* silenced flies (Fig. 7B). Significantly, these
469 data were reinforced by electron microscopy, revealing a disordered structure of the cuticular
470 lining of these tracheoles (Fig.7C). We hypothesize that in the absence of the Vajk1, the chitin
471 cannot be properly embedded in the cuticle, hence resulting in a disorganized structure to the
472 cuticular layer.

473 In our opinion the classification of the Vajk proteins in a cuticular protein family is not
474 completely clear. Many Vajk protein orthologs (Fig. 1, Table 2) were assigned to the CPG
475 family. Moreover the three Vajk orthologs from *Anopheles gambiae* (Fig. 1, Table 2) belong to
476 the CPLCP family. Members of this family have a high density of PV and PY pairs (Cornman
477 and Willis, 2009; Willis, 2010), which is also characteristic for each Vajk protein. Surprisingly
478 the Vajk consensus sequence shown in Fig. 1C is present in the listed CPG and also CPLCP
479 proteins.

480 In this work we show that all *vajk* genes are transcribed in the embryo, first and second stage
481 larvae, pupae, as well as in one day old adults. Moreover, we show that the Vajk proteins are
482 present in structures known to contain cuticle. It is conceivable that in the tracheoles running
483 along the indirect flight muscles of the pharate adults, the presence of the Vajk1 protein is
484 essential, because the observed cuticular structure is accompanied with pupal lethality. Moreover
485 we suppose that the cuticular localization of the Vajk proteins might also serve as the first,
486 mechanical barrier to protect the organism from the harmful environmental aspects, thus achieved
487 a concerted action with the previously characterized proteins encoded by the Nimrod cluster.

488

648 **Figure and table captions:**

649 **Fig. 1.** Sequence analysis of the Vajk proteins and their orthologs. (A) The identical repetitive
 650 segments are marked with the same colors in bold and/or are underlined. (B) In the alignment, the
 651 identified consensus sequence is highlighted in bold and the sequences including repetitive
 652 segments are underlined. (C) The Vajk specific consensus sequence is also present in the Vajk
 653 orthologs of other species. The residues indicated with regular characters on gray background
 654 share similar properties with the consensus specific amino acids. Abbreviations: *Ag*, *Anopheles*
 655 *gambiae*; *Bm*, *Bombyx mori*; *Dp*, *Danaus plexippus*; *Ob*, *Operophtera brumata*; *Pp*, *Papilio*
 656 *polytes*; *Px*, *Papilio xuthus*. Sequence analysis was done using CLUSTALW Multiple Sequence
 657 Alignment (<http://www.genome.jp/tools/clustalw/>).

658

659 **Fig. 2.** Analysis of the *vajk* gene expression in the (A) hemocytes of the third instar *l(3)mbn-1*
 660 larvae and in (B) different developmental stages of the Oregon R *D. melanogaster*. Agarose gel
 661 electrophoresis of the RT-PCR products obtained with primer pairs specific for both RA and RB
 662 *vajk-1* transcripts, the *vajk-2*, *vajk-3* and *vajk-4* transcripts, generating 1031, 828, 849, and 1003
 663 bp fragments respectively. As positive controls for the cDNA, the *Hemese* specific (175 bp) (A)
 664 and rp49 specific (316 bp) (B) primer sets were used. To test the *vajk* specific primer sets, vectors
 665 containing *vajk* cDNAs were used as templates (positive controls). Negative control reactions
 666 include water as templates.

667

668 **Fig 3.** Localization of the Vajk1 (A) and Vajk4 (B) proteins in the 16-17 stage embryo. Both
 669 proteins were detected in the trachea (tr) and the denticle belt areas of the ventral epidermis (db).
 670 Moreover the Vajk1 protein was also detected in the esophagus (eg) and the ducts of the salivary
 671 glands (sd). As controls normal mouse serum (C) and anti-tubulin mouse monoclonal antibody
 672 (D) were used. The secondary antibody was Alexa Fluor 488 goat-anti-mouse IgG (green).
 673 Nuclear staining is blue. Images were obtained with Confocal LSM. The scalebar represents 100
 674 μm .

675

676 **Fig. 4.** Expression of the Vajk1 protein in 72 h old pupae. (A, B) Vajk1 (far red) co-localizes
 677 with the *btl* promoter activity (green). Indirect flight muscles were analyzed with Confocal LSM.

678 The used line carried the *Btl-GAL4*, the *UAS-GFPn* and the *Flip-FRT* lineage tracing construct
 679 system (*Btl>AFG>GFP*). A, A' and A'' images were stained with antibodies against the Vajk1
 680 protein, and B, B' and B'', with the normal mouse serum. As secondary antibodies Alexa Fluor
 681 633 goat-anti-mouse IgG (far red) were used. The scalebar represents 50 μm . (C) Surface plot of
 682 *btl* activity and Vajk1 localization (ImageJ). The scalebars represents 8 μm . (D)
 683 Immunohistochemical analysis of the indirect flight muscle following RNA interference at 29 °C.
 684 After the treatment with the primary antibodies, streptavidin/HRP and biotinilated polyclonal
 685 goat anti-mouse immunoglobulins were used. The chromogen was 3-amino 9-ethylcharbasole.
 686 The scalebar represents 100 μm . (E) Western blot analysis of the lysates prepared after *vajk-1*
 687 RNA inhibition.

688
 689 **Fig. 5.** Expression of the Vajk4 protein in 72 h old pupae. (A, B) Analysis of the protein with
 690 indirect immunofluorescence. (A) The protein is expressed in the epidermal tissue of the pharate
 691 adults. Hair cells are marked with arrows. Alexa Fluor 488 goat-anti mouse IgG (green) was used
 692 as secondary antibody. Nuclear staining is blue. (B) Analysis of the Vajk4 protein after gene
 693 silencing at 29 °C. Scalebars represent 100 μm . (C) Western blot analysis of the Vajk4 following
 694 gene silencing.

695
 696 **Fig. 6.** Western blot analysis of the Vajk1 and Vajk4 proteins in different developmental stages
 697 of *D. melanogaster*.

698
 699 **Fig. 7.** Functional analysis of the Vajk proteins. (A) Vajk1 and Vajk4 proteins bind to chitin.
 700 Chitin binding assays were carried out on recombinant, C terminally FLAG tagged, Vajk and
 701 NimC1 proteins as described in Materials and methods. Inp, input protein sample; Ft, flow
 702 through; W, the fifth wash of the chitin beads; Elu, fraction eluted with 8M urea. (B) Thoracic
 703 cross-sections at stage P15, showing dorsal longitudinal flight muscles labelled for Nidogen
 704 (Nido, red) to visualize the basement membrane and chitin (CBP, green) to mark the tracheal
 705 terminal branch tracheoles that innervate the muscles (arrows). The presence of CBP-labelled
 706 tracheoles is reduced upon expression of *vajk-1* RNAi compared to control flies. Scale bar
 707 represents 10 μm . (C) Electron micrographs of the longitudinally sectioned tracheloae localized
 708 in the indirect flight muscles. The epicuticle (ep), procuticle (pc), basal procuticular surface (ps)

709 and the taenidia (ta) are normally organized in the parental lines (*102445/KK* and *Da-GAL4*) as
710 opposed to the remarkably disordered assembly in the *vajk-1* silenced samples
711 (*102445/KK/+;Da-GAL4/+*). lm, indicates the tracheolar lumen. Scale bar represents 1 μm .

712

713 **Table 1**

714 Primers used in this work. Adapter restriction sites are marked with bold.

715

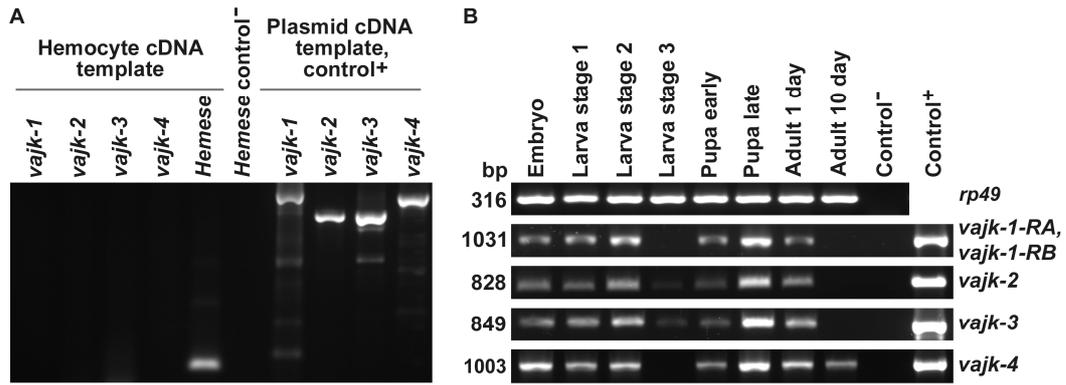

716 **Table 2**

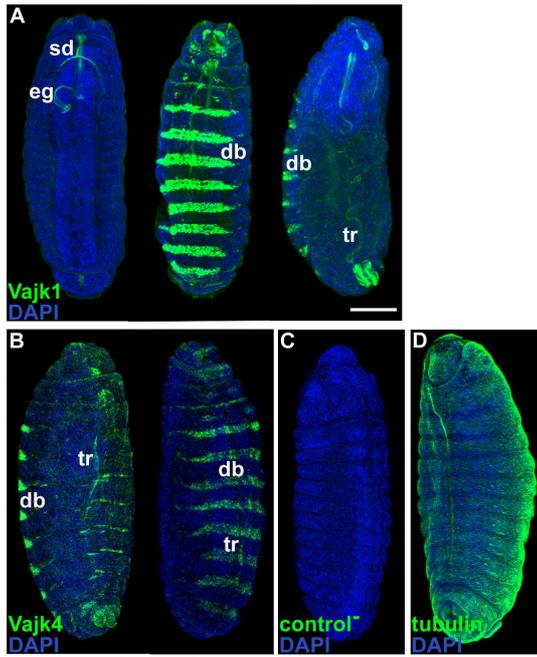

717 Sequence analysis of the Vajk orthologs, concerning the repetitive blocks of the Vajk proteins.

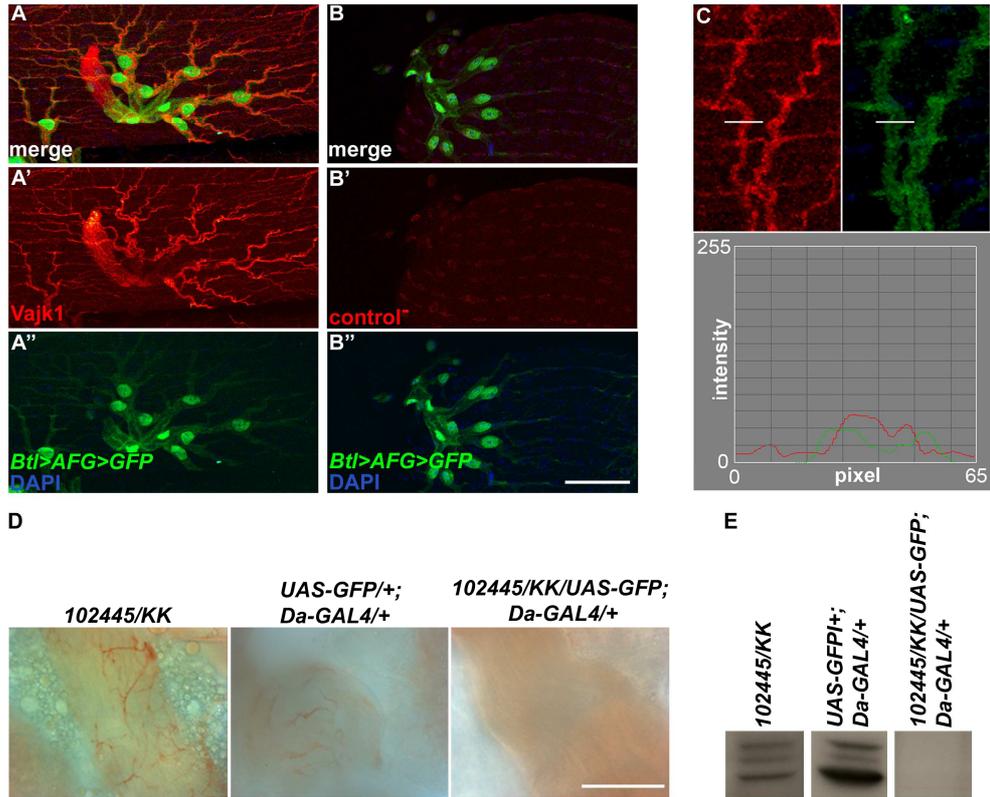

718 Abbreviations: +, present; -, not present; the species used are described in the legend of Fig. 1.

- The Nimrod gene cluster is the largest syntenic unit of the *Drosophila* genome.
- The *Nim* and *Hemese* genes of the cluster are involved in the regulation of innate immunity and cell adhesion.
- Vajk proteins are encoded by genes in the Nimrod cluster and are expressed in cuticular structures and possibly contribute to barrier function.
- Genes of the Nimrod region may regulate different layers of defense in a concerted action.
