# DIOPHANTINE EQUATIONS WITH APPELL SEQUENCES 

## ANDRÁS BAZSÓ AND ISTVÁN PINK

#### Abstract

We consider the Diophantine equation $P_{n}(x)=g(y)$ in $x, y$ where $P_{n}(x), g(x) \in \mathbb{Q}[x], \operatorname{deg} g(x) \geq 3$ and $\left\{P_{n}(x)\right\}_{n \geq 0}$ is an Appell sequence. Under some reasonable assumptions on $\bar{P}_{n}(x)$ we prove an ineffective finiteness result on the above equation.

## 1. Introduction

For $n \in \mathbb{N} \cup\{0\}$, let $P_{n}(x)$ be a polynomial with rational coefficients and with $\operatorname{deg} P_{n}(x)=n$. Further, let $P_{0}(x)$ be a non-zero constant. The sequence $\left\{P_{n}(x)\right\}_{n \geq 0}$ is called an Appell sequence (and $P_{n}(x)$ is called an Appell polynomial) if

$$
\begin{equation*}
P_{n}^{\prime}(x)=n P_{n-1}(x) \quad \text { for all } n \in \mathbb{N} . \tag{1}
\end{equation*}
$$

The history of such polynomials goes back to Appell's work [2] in 1880. There are several well-known examples of Appell sequences, such as the Bernoulli polynomials $B_{n}(x)$, the Euler polynomials $E_{n}(x)$, and the Hermite polynomials $H_{n}(x)$, respectively defined by the following generating series (see e.g. [12])

$$
\begin{gathered}
\frac{t \exp (t x)}{\exp (t)-1}=\sum_{n=0}^{\infty} B_{n}(x) \frac{t^{n}}{n!} ; \\
\frac{2 \exp (x t)}{\exp (t)+1}=\sum_{n=0}^{\infty} E_{n}(x) \frac{t^{n}}{n!} \quad(|t|<\pi) ; \\
\frac{\exp (t x)}{\exp \left(t^{2} / 2\right)}=\sum_{n=0}^{\infty} H_{n}(x) \frac{t^{n}}{n!} .
\end{gathered}
$$

The above defined Hermite polynomials $H_{n}(x)$ are sometimes denoted by $H e_{n}(x)$, e.g. in the book of Abramowitz and Stegun [1].

The following properties of Appell polynomials will often be used in the text, sometimes without special reference.

[^0]We recall the so-called Appell Identity:

$$
\begin{equation*}
P_{n}(x+y)=\sum_{k=0}^{n}\binom{n}{k} P_{k}(x) y^{n-k}=\sum_{k=0}^{n}\binom{n}{k} P_{k}(y) x^{n-k} \tag{2}
\end{equation*}
$$

which, by setting $y=0$, implies that there exists a sequence of rational numbers $\left\{c_{n}\right\}_{n \geq 0}$ with $c_{0} \neq 0$ such that

$$
\begin{equation*}
P_{n}(x)=\sum_{k=0}^{n}\binom{n}{k} c_{k} x^{n-k}, \quad \text { where } c_{k}:=P_{k}(0)(k \geq 0) \tag{3}
\end{equation*}
$$

For the proofs of (2) and (3) see, for instance the book of Roman [12].
Let $\mathbb{K}$ be an arbitrary field. We denote by $\mathbb{K}[x]$ the ring of polynomials in the variable $x$ with coefficients from $\mathbb{K}$. A decomposition of a polynomial $F(x)$ over $\mathbb{K}$ is an equality of the following form

$$
F(x)=G_{1}\left(G_{2}(x)\right) \quad\left(G_{1}(x), G_{2}(x) \in \mathbb{K}[x]\right),
$$

which is nontrivial if

$$
\operatorname{deg} G_{1}(x)>1 \quad \text { and } \quad \operatorname{deg} G_{2}(x)>1
$$

Two decompositions $F(x)=G_{1}\left(G_{2}(x)\right)$ and $F(x)=H_{1}\left(H_{2}(x)\right)$ are said to be equivalent if there exists a linear polynomial $\ell(x) \in \mathbb{K}[x]$ such that $G_{1}(x)=H_{1}(\ell(x))$ and $H_{2}(x)=\ell\left(G_{2}(x)\right)$. The polynomial $F(x)$ is called decomposable over $\mathbb{K}$ if it has at least one nontrivial decomposition over $\mathbb{K}$; otherwise it is said to be indecomposable.

The decomposition of Bernoulli polynomials has been described by Bilu et al. in [6]. Decomposition properties of Euler polynomials were recently investigated by Rakaczki and Kreso [11]. The mentioned results can both be summarized as follows: the corresponding polynomial $\left(B_{n}(x)\right.$ or $\left.E_{n}(x)\right)$ is indecomposable over $\mathbb{C}$ for all odd $n$, while, if $n$ is even, then any nontrivial decomposition of the polynomial under consideration over $\mathbb{C}$ is equivalent to one of the shape

$$
\widehat{P}_{n / 2}\left(\left(x-\frac{1}{2}\right)^{2}\right)
$$

where $\widehat{P}_{n / 2}(x)$ is a polynomial of degree $n / 2$ which is indecomposable for every $n$. These results from [6] and [11] suggest the following notion. We say that an Appell sequence $\left\{P_{n}(x)\right\}_{n>0}$ is of special type if $P_{n}(x)$ is indecomposable over $\mathbb{C}$ for all odd $n$, and, for even $n$, every nontrivial decomposition of $P_{n}(x)$ is equivalent to a decomposition of the form

$$
\begin{equation*}
P_{n}(x)=\widehat{P}_{n / 2}\left(\left(x-\frac{1}{2}\right)^{2}\right) \tag{4}
\end{equation*}
$$

with an indecomposable polynomial $\widehat{P}_{n / 2}(x)$ over $\mathbb{C}$ of degree $n / 2$. Clearly, the polynomials $\left\{B_{n}(x)\right\}_{n>0}$ and $\left\{E_{n}(x)\right\}_{n>0}$ are of special type.

The theory of polynomial decomposition is strongly connected to the theory of separable Diophantine equations since, in 2000, Bilu and Tichy [5] established their general ineffective finiteness criterion on equations of the form $f(x)=g(y)$. (See Proposition 1 below.)

In this paper we study the Diophantine equation

$$
\begin{equation*}
P_{n}(x)=g(y) \quad \text { in integers } x, y \tag{5}
\end{equation*}
$$

where $P_{n}(x)$ is from an Appell sequence of special type and $g(x) \in \mathbb{Q}[x]$, $\operatorname{deg} g(x) \geq 3$. For technical reasons, we restrict ourselves to Appell sequences $\left\{P_{n}(x)\right\}_{n \geq 0}$ for which

$$
\begin{equation*}
\frac{3 P_{2}\left(-c_{1} / c_{0}\right)^{2}-2 c_{0} P_{4}\left(-c_{1} / c_{0}\right)}{3 P_{2}\left(-c_{1} / c_{0}\right)^{2}-c_{0} P_{4}\left(-c_{1} / c_{0}\right)} \quad \text { is not a positive integer. } \tag{6}
\end{equation*}
$$

Remark. In the following table, we give the value of the constant from (6) for the case when $P_{n}(x)$ is a Bernoulli, Euler or an Hermite polynomial, respectively.

$$
\begin{array}{c|c|c}
B_{n}(x) & E_{n}(x) & H_{n}(x) \\
\hline 9 / 2 & 7 / 2 & \text { undefined }
\end{array}
$$

For $P_{n}(x)=B_{n}(x)$, Rakaczki [10], and independently Kulkarni and Sury [9] characterized those pairs ( $n, g(y)$ ) for which equation (5) has infinitely many integer solutions. Recently, Rakaczki and Kreso [11] proved an analogous result for the case when $P_{n}(x)=\left(E_{n}(0) \pm E_{n}(x)\right) / 2$ (which is not an Appell polynomial anymore). For further related results we refer to $[7,8]$.

We prove the following.
Theorem 1. Let $g(x) \in \mathbb{Q}[x]$ with $\operatorname{deg} g(x) \geq 3$, and suppose that $\left\{P_{n}(x)\right\}_{n \geq 0}$ is an Appell sequence of special type with property (6). Then for $n \geq 7$, equation (5) has only finitely many integer solutions $x, y$, apart from the following cases:
(i) $g(x)=P_{n}(h(x))$, where $h(x)$ is a polynomial over $\mathbb{Q}$.
(ii) $g(x)=\gamma\left(\delta(x)^{m}\right)$, where $m$ is a positive integer.
(iii) $n$ is even and $g(x)=\widehat{P}_{n / 2}\left(q(x)^{2}\right)$
(iv) $n$ is even and $g(x)=\widehat{P}_{n / 2}\left(\delta(x) q(x)^{2}\right)$
(v) $n$ is even and $g(x)=\widehat{P}_{n / 2}\left(c \delta(x)^{t}\right)$, where $t \geq 3$ is an odd integer
(vi) $n$ is even and $g(x)=\widehat{P}_{n / 2}\left(\left(a \delta(x)^{2}+b\right) q(x)^{2}\right)$

Here $a, b, c \in \mathbb{Q} \backslash\{0\}, \gamma(x), \delta(x) \in \mathbb{Q}[x]$ are linear polynomials and $q(x) \in \mathbb{Q}[x]$ is a non-zero polynomial.

We prove the above theorem by applying among other things the general finiteness criterion of Bilu and Tichy [5] for equation (5). Hence our finiteness result is ineffective.

Remark. For $n \geq 7$, our main result is a common generalization of the mentioned results of Rakaczki [10], Kulkarni and Sury [9] and Rakaczki and Kreso [11]. In the special cases $P_{n}(x) \in\left\{B_{n}(x), E_{n}(x)\right\}$, one can exclude the exceptional case (ii) by making use of some specific properties of the Bernoulli or Euler polynomials, respectively. (See $[9,10,11])$

## 2. Auxiliary results

Before proving Theorem 1, we collect those results that we are going to apply in the proof. First, we recall the finiteness criterion of Bilu and Tichy [5]. To do this, we need to define five kinds of so-called standard pairs of polynomials.

Let $\alpha, \beta$ be nonzero rational numbers, $\mu, \nu, q>0$ and $r \geq 0$ be integers, and let $v(x) \in \mathbb{Q}[x]$ be a nonzero polynomial (which may be constant). Denote by $D_{\mu}(x, \delta)$ the $\mu$-th Dickson polynomial, defined by the functional equation $D_{\mu}(z+\delta / z, \delta)=z^{\mu}+(\delta / z)^{\mu}$ or by the explicit formula

$$
D_{\mu}(x, \delta)=\sum_{i=0}^{\lfloor\mu / 2\rfloor} d_{\mu, i} x^{\mu-2 i} \quad \text { with } \quad d_{\mu, i}=\frac{\mu}{\mu-i}\binom{\mu-i}{i}(-\delta)^{i} .
$$

Two polynomials $f_{1}(x)$ and $g_{1}(x)$ are said to form a standard pair over $\mathbb{Q}$ if one of the ordered pairs $\left(f_{1}(x), g_{1}(x)\right)$ or $\left(g_{1}(x), f_{1}(x)\right)$ belongs to the list below. The five kinds of standard pairs are then listed in the following table.

| kind | explicit form of $\left\{f_{1}(x), g_{1}(x)\right\}$ | parameter restrictions |
| :--- | :--- | :--- |
| first | $\left(x^{q}, \alpha x^{r} v(x)^{q}\right)$ | $0 \leq r<q,(r, q)=1$, <br> $r+\operatorname{deg} v(x)>0$ |
| second | $\left(x^{2},\left(\alpha x^{2}+\beta\right) v(x)^{2}\right)$ | - |
| third | $\left(D_{\mu}\left(x, \alpha^{\nu}\right), D_{\nu}\left(x, \alpha^{\mu}\right)\right)$ | $(\mu, \nu)=1$ |
| fourth | $\left(\alpha^{\frac{-\mu}{2}} D_{\mu}(x, \alpha),-\beta^{\frac{-\nu}{2}} D_{\nu}(x, \beta)\right)$ | $(\mu, \nu)=2$ |
| fifth | $\left(\left(\alpha x^{2}-1\right)^{3}, 3 x^{4}-4 x^{3}\right)$ | - |

The following proposition is a special case of the main result of [5].
Proposition 1. Let $f(x), g(x) \in \mathbb{Q}[x]$ be nonconstant polynomials such that the equation $f(x)=g(y)$ has infinitely many solutions in rational integers $x, y$. Then $f=\varphi \circ f_{1} \circ \lambda$ and $g=\varphi \circ g_{1} \circ \mu$,
where $\lambda(x), \mu(x) \in \mathbb{Q}[x]$ are linear polynomials, $\varphi(x) \in \mathbb{Q}[x]$, and $\left(f_{1}(x), g_{1}(x)\right)$ is a standard pair over $\mathbb{Q}$.

For $P(x) \in \mathbb{C}[x]$, a complex number $c$ is said to be an extremum if $P(x)-c$ has multiple roots. The $P$-type of $c$ is defined to be the tuple $\left(\alpha_{1}, \ldots, \alpha_{s}\right)$ of the multiplicities of the distinct roots of $P(x)-c$ in an increasing order. Obviously, $s<\operatorname{deg} P(x)$ and $\alpha_{1}+\ldots+\alpha_{s}=\operatorname{deg} P(x)$.
Proposition 2. For $a \neq 0$ and $k \geq 3, D_{\mu}(x, \alpha)$ has exactly two extrema $\pm 2 \alpha^{\frac{\mu}{2}}$. If $\mu$ is odd, then both are of P-type $(1,2,2, \ldots, 2)$. If $\mu$ is even, then $2 \alpha^{\frac{\mu}{2}}$ is of $P$-type $(1,1,2, \ldots, 2)$ and $-2 \alpha^{\frac{\mu}{2}}$ is of $P$-type $(2,2, \ldots, 2)$.
Proof. See, for instance [4, Proposition 3.3].
We end this section with two technical results. Let $d_{1}, e_{1} \in \mathbb{Q}^{*}$ and $d_{0}, e_{0} \in \mathbb{Q}$

Proposition 3. Suppose that $\left\{P_{n}(x)\right\}_{n \geq 0}$ is an Appell sequence of special type. Then the polynomial $P_{n}\left(d_{1} x+d_{0}\right)$ is not of the form $e_{1} x^{q}+e_{0}$, with $q \geq 7$.
Proof. We assume the contrary, i.e., that we have

$$
\begin{equation*}
P_{n}\left(d_{1} x+d_{0}\right)=e_{1} x^{q}+e_{0} \tag{7}
\end{equation*}
$$

with $q \geq 7$. Obviously, we then have $n=q$.
We observe from (2) and (7) that

$$
\begin{equation*}
P_{1}\left(d_{0}\right)=P_{2}\left(d_{0}\right)=\ldots=P_{n-1}\left(d_{0}\right)=0 . \tag{8}
\end{equation*}
$$

Since, by (3), $P_{1}\left(d_{0}\right)=c_{0} d_{0}+c_{1}$, we get

$$
\begin{equation*}
d_{0}=-\frac{c_{1}}{c_{0}} . \tag{9}
\end{equation*}
$$

Further, since, by (1),

$$
\begin{equation*}
P_{k}(x)=\frac{k!}{(n-1)!} P_{n-1}^{(n-1-k)}(x), \quad k=1, \ldots, n-1, \tag{10}
\end{equation*}
$$

we infer that $d_{0}$ is a root of $P_{n-1}(x)$ of multiplicity $(n-1)$. Thus, in view of (9), we have $P_{n-1}(x)=c_{0}\left(x+c_{1} / c_{0}\right)^{n-1}$, which implies

$$
\begin{equation*}
P_{n}(x)=c_{0}\left(x+\frac{c_{1}}{c_{0}}\right)^{n}+C \quad \text { with } \quad C=P_{n}\left(-\frac{c_{1}}{c_{0}}\right) . \tag{11}
\end{equation*}
$$

First, if $n \geq 7$ is even, then, by (11), one can easily find the nontrivial decomposition $P_{n}(x)=Q(R(x))$ with

$$
\begin{equation*}
Q(x)=c_{0} x^{2}+C, \quad \text { and } \quad R(x)=\left(x+\frac{c_{1}}{c_{0}}\right)^{n / 2} \tag{12}
\end{equation*}
$$

Since $n \geq 7$, this nontrivial decomposition is obviously not equivalent to the one in (4), contradicting that $\left\{P_{n}(x)\right\}_{n>0}$ is of special type.

Now, let $n \geq 7$ be an odd positive integer. If $n$ is composite, then any divisor $v$ of $n$ with $1<v<n$ leads to a nontrivial decomposition

$$
\begin{equation*}
P_{n}(x)=c_{0}\left(\left(x+\frac{c_{1}}{c_{0}}\right)^{v}\right)^{n / v}+C \tag{13}
\end{equation*}
$$

which again contradicts that $\left\{P_{n}(x)\right\}_{n \geq 0}$ is of special type (and in this case $P_{n}(x)$ is indecomposable). If $n$ is a prime, then derivating both sides of (11) we obtain

$$
\begin{equation*}
P_{n-1}(x)=c_{0}\left(x-\frac{1}{2}\right)^{n-1} \tag{14}
\end{equation*}
$$

where of course the exponent $n-1$ is even. Similarly as above, this leads to a nontrivial decomposition not equivalent to (4) and thus to a contradiction.

Proposition 4. Suppose that $\left\{P_{n}(x)\right\}_{n>0}$ is an Appell sequence which satisfies (6). Then the polynomial $P_{n}\left(d_{1} x+d_{0}\right)$ is not of the form $e_{1} D_{\mu}(x, \delta)+e_{0}$, where $D_{\mu}(x, \delta)$ the $\mu$-th Dickson polynomial with $\mu>4$, $\delta \in \mathbb{Q}^{*}$.

Proof. Suppose that the Appell sequence $\left\{P_{n}(x)\right\}_{n \geq 0}$ satisfies (6), and that we have

$$
\begin{equation*}
P_{n}\left(d_{1} x+d_{0}\right)=e_{1} D_{\mu}(x, \delta)+e_{0} . \tag{15}
\end{equation*}
$$

Clearly, $n=\mu$. Comparing the leading coefficients of both sides we get

$$
\begin{equation*}
d_{1}^{n} c_{0}=e_{1}, \tag{16}
\end{equation*}
$$

where the numbers $c_{k}(k \geq 0)$ are defined in (3). Similarly, from (2) and the equality of the coefficients of $x^{n-1}$ on both sides we obtain

$$
\begin{equation*}
n d_{1}^{n-1} P_{1}\left(d_{0}\right)=0, \tag{17}
\end{equation*}
$$

which implies

$$
\begin{equation*}
d_{0}=-\frac{c_{1}}{c_{0}} . \tag{18}
\end{equation*}
$$

Again, by (2), comparing the coefficients of $x^{n-2}$ gives

$$
\begin{equation*}
\binom{n}{2} d_{1}^{n-2} P_{2}\left(d_{0}\right)=-e_{1} n \delta \tag{19}
\end{equation*}
$$

whence, together with (16) it follows that

$$
\begin{equation*}
d_{1}^{2}=-\frac{(n-1) P_{2}\left(d_{0}\right)}{2 c_{0} \delta} \tag{20}
\end{equation*}
$$

Now we compare the coefficients of $x^{n-4}$ on both sides of (15) and we obtain

$$
\begin{equation*}
\binom{n}{4} d_{1}^{n-4} P_{4}\left(d_{0}\right)=\frac{e_{1} n(n-3) \delta^{2}}{2}, \tag{21}
\end{equation*}
$$

which along with (16) leads to

$$
\begin{equation*}
d_{1}^{4}=\frac{(n-1)(n-2) P_{4}\left(d_{0}\right)}{12 c_{0} \delta^{2}} . \tag{22}
\end{equation*}
$$

After substituting (20) into (22), we obtain

$$
\begin{equation*}
3(n-1) P_{2}\left(d_{0}\right)^{2}=(n-2) c_{0} P_{4}\left(d_{0}\right), \tag{23}
\end{equation*}
$$

whence, together with (18) it follows that

$$
\begin{equation*}
n=\frac{3 P_{2}\left(-c_{1} / c_{0}\right)^{2}-2 c_{0} P_{4}\left(-c_{1} / c_{0}\right)}{3 P_{2}\left(-c_{1} / c_{0}\right)^{2}-c_{0} P_{4}\left(-c_{1} / c_{0}\right)} . \tag{24}
\end{equation*}
$$

This is a contradiction by (6).
We note that Proposition 4 is a common generalization of Lemma 5.3 in [6], Lemma 2.4 in [3], and of the second statement of Lemma 12 in [11].

## 3. Proof of Theorem 1

Let $g(x) \in \mathbb{Q}[x]$ with $\operatorname{deg} g(x) \geq 3$. Suppose that equation (5) has infinitely many integer solutions $x, y$ with an Appell sequence $\left\{P_{n}(x)\right\}_{n \geq 0}$ of special type satisfying (6) and with $n \geq 7$. Then by Proposition 1 it follows that there exist $\lambda(x), \mu(x), \varphi(x) \in \mathbb{Q}[x]$, $\operatorname{deg} \lambda(x)=\operatorname{deg} \mu(x)=1$ such that

$$
\begin{equation*}
P_{n}(x)=\varphi\left(f_{1}(\lambda(x))\right) \quad \text { and } \quad g(x)=\varphi\left(g_{1}(\mu(x))\right), \tag{25}
\end{equation*}
$$

where $\left(f_{1}(x), g_{1}(x)\right)$ is a standard pair over $\mathbb{Q}$.
Let $\lambda^{-1}(x)=a_{1} x+a_{0}, \mu^{-1}(x)=b_{1} x+b_{0}$, where $a_{0}, a_{1}, b_{0}, b_{1} \in \mathbb{Q}$ with $a_{1} b_{1} \neq 0$. Then we can rewrite (25) as

$$
\begin{equation*}
P_{n}\left(a_{1} x+a_{0}\right)=\varphi\left(f_{1}(x)\right) \quad \text { and } \quad g\left(b_{1} x+b_{0}\right)=\varphi\left(g_{1}(x)\right), \tag{26}
\end{equation*}
$$

Since $P_{n}(x)$ is of special type and $\operatorname{deg} P_{n}(x)=n$, we obtain that

$$
\operatorname{deg} \varphi(x) \in\left\{1, \frac{n}{2}, n\right\}
$$

3.1. The case $\operatorname{deg} \varphi(x)=n$. If we assume that $\operatorname{deg} \varphi(x)=n$, then by (25), we have $\operatorname{deg} f_{1}(x)=1$. Thus $P_{n}(x)=\varphi(t(x))$, where $t(x) \in \mathbb{Q}[x]$ is a linear polynomial. Clearly, $t^{-1}(x) \in \mathbb{Q}[x]$ is also linear. By (25), we obtain $P_{n}\left(t^{-1}(x)\right)=\varphi\left(t\left(t^{-1}(x)\right)\right)=\varphi(x)$. Hence

$$
\begin{equation*}
g(x)=\varphi\left(g_{1}(\mu(x))\right)=P_{n}\left(t^{-1}\left(g_{1}(\mu(x))\right)\right)=P_{n}(q(x)), \tag{27}
\end{equation*}
$$

where $q(x)=t^{-1}\left(g_{1}(\mu(x))\right)$. So, if, in our case, equation (5) has infinitely many solutions, then $g(x)$ is of the form as in Theorem 1 (i).
3.2. The case $\operatorname{deg} \varphi(x)=1$. Let $\varphi(x)=\varphi_{1} x+\varphi_{0}$, where $\varphi_{1}, \varphi_{0} \in \mathbb{Q}$ and $\varphi_{1} \neq 0$. We study now the five kinds of standard pairs.

In view of our assumptions on $n$ and $\operatorname{deg} g(x)$, it follows that the standard pair $\left(f_{1}(x), g_{1}(x)\right)$ cannot be of the second or fifth kind.

If it is of the third or fourth kind, we then have $P_{n}\left(a_{1} x+a_{0}\right)=$ $e_{1} D_{\mu}(x, \delta)+e_{0}$ with $e_{0} \in \mathbb{Q}, e_{1}, \delta \in \mathbb{Q}^{*}$. This contradicts Proposition 4.

If $\left(f_{1}(x), g_{1}(x)\right)$ is a standard pair of the first kind, then we have either
(I) $P_{n}\left(a_{1} x+a_{0}\right)=\varphi_{1} x^{q}+\varphi_{0}$, or
(II) $P_{n}\left(a_{1} x+a_{0}\right)=\varphi_{1} \alpha x^{p} \nu(x)^{q}+\varphi_{0}$, where $0 \leq p<q,(p, q)=1$ and $p+\operatorname{deg} \nu(x)>0$.
The first case (I) is impossible by Proposition 3 since $n \geq 7$ by assumption.

Let us now consider the second case (II). Then we have $g(x)=$ $\varphi_{1} \mu(x)^{q}+\varphi_{0}=\varphi\left(\mu(x)^{q}\right)$, where $q \geq 3$ and $\mu(x) \in \mathbb{Q}[x]$ is linear, which is case (ii) of Theorem 1.
3.3. The case $\operatorname{deg} \varphi(x)=n / 2$. Clearly, $n$ is then even, and from (25) we observe that $\operatorname{deg} f_{1}(x)=2$. Hence it follows that, in (25), $\left(f_{1}(x), g_{1}(x)\right)$ cannot be a standart pair of the fifth kind. Further, we obtain a nontrivial decomposition of $P_{n}(x)$, which, since $P_{n}(x)$ is of special type, implies that there exists a linear polynomial $\ell(x)=\ell_{1} x+\ell_{0}$ over $\mathbb{Q}$ such that

$$
\begin{equation*}
\varphi(x)=\widehat{P}_{n / 2}(\ell(x)) \quad \text { and } \quad \ell\left(f_{1}(\lambda(x))\right)=\left(x-\frac{1}{2}\right)^{2} . \tag{28}
\end{equation*}
$$

Again, we study the remaining kinds of standard pairs.
First, we consider the case when, in (25), $\left(f_{1}(x), g_{1}(x)\right)$ is a standard pair of the first kind. If $f_{1}(x)=x^{t}$, then by $\operatorname{deg} f_{1}(x)=2$, we have $\left(f_{1}(x), g_{1}(x)\right)=\left(x^{2}, \alpha x p(x)^{2}\right)$. Putting $\lambda(x)=\lambda_{1} x+\lambda_{0}$, (28) takes the form $\ell\left(\left(\lambda_{1} x+\lambda_{0}\right)^{2}\right)=(x-1 / 2)^{2}$, whence an easy calculation gives
$\ell(x)=x / \lambda_{1}^{2}$. Substituting this to (25), we obtain

$$
\begin{equation*}
g(x)=\widehat{P}_{n / 2}\left(\ell\left(g_{1}(\mu(x))\right)\right)=\widehat{P}_{n / 2}\left(\frac{\alpha \mu(x) p(\mu(x))^{2}}{\lambda_{1}^{2}}\right) \tag{29}
\end{equation*}
$$

So $g(x)$ is of the form (iv) with $\delta(x)=\alpha \mu(x) / \lambda_{1}^{2}$ and $q(x)=p(\mu(x))$.
In the switched case $\left(f_{1}(x), g_{1}(x)\right)=\left(\alpha x^{r} p(x)^{t}, x^{t}\right)$, where $0 \leq r<t$, $(r, t)=1$ and $r+\operatorname{deg} p(x)>0, \operatorname{deg} f_{1}(x)=2$ implies that one of the following cases occurs:
(A) $r=0, t=1$ and $\operatorname{deg} p(x)=2$, or
(B) $r=2, t>2$ is odd and $p(x)$ is a constant polynomial.

In case (A) we have $g_{1}(x)=x$, whence from (25) and (28) we obtain

$$
\begin{equation*}
g(x)=\widehat{P}_{n / 2}\left(\ell\left(g_{1}(\mu(x))\right)\right)=\widehat{P}_{n / 2}(\ell(\mu(x)))=\widehat{P}_{n / 2}\left(\delta(x) q(x)^{2}\right) \tag{30}
\end{equation*}
$$

where $\delta(x)=\ell(\mu(x))$ and $q(x) \equiv 1$. Thus $g(x)$ is again of the form (iv).

In the second case (B), we can write $f_{1}(x)=\beta x^{2}$, with $\beta=\alpha p(x)^{t} \in$ $\mathbb{Q} \backslash\{0\}$. Substituting this to (28), we deduce that $\ell(x)=x /\left(\beta \lambda_{1}^{2}\right)$, whence, by (25), we get

$$
\begin{equation*}
g(x)=\widehat{P}_{n / 2}\left(\ell\left(g_{1}(\mu(x))\right)\right)=\widehat{P}_{n / 2}\left(\frac{\mu(x)^{t}}{\beta \lambda_{1}^{2}}\right)=\widehat{P}_{n / 2}\left(c \delta(x)^{t}\right), \tag{31}
\end{equation*}
$$

where $c=1 /\left(\beta \lambda_{1}^{2}\right), \delta(x)=\mu(x)$ and $t>2$ is odd. This is option (v) in Theorem 1.

Next let, in (25), be a the standard pair $\left(f_{1}(x), g_{1}(x)\right)$ of the second kind. If $\left(f_{1}(x), g_{1}(x)\right)=\left(x^{2},\left(\alpha x^{2}+\beta\right) v(x)^{2}\right)$, then a calculation from (28) yields $\ell(x)=x / \lambda_{1}^{2}$, and by (25) we have

$$
\begin{align*}
& g(x)=\widehat{P}_{n / 2}\left(\ell\left(g_{1}(\mu(x))\right)\right)= \\
& =\widehat{P}_{n / 2}\left(\frac{\left(\alpha \mu(x)^{2}+\beta\right) v(\mu(x))^{2}}{\lambda_{1}^{2}}\right)=\widehat{P}_{n / 2}\left(\left(\alpha \delta(x)^{2}+\beta\right) q(x)^{2}\right), \tag{32}
\end{align*}
$$

where $\delta(x)=\mu(x)$ and $q(x)=v(\mu(x)) / \lambda_{1}$. So we are led to option (vi) of our theorem.

In the switched case $\left(f_{1}(x), g_{1}(x)\right)=\left(\left(\alpha x^{2}+\beta\right) v(x)^{2}, x^{2}\right)$, since $\operatorname{deg} f_{1}(x)=2, v(x)$ is a constant polynomial and

$$
\begin{equation*}
g(x)=\widehat{P}_{n / 2}\left(\ell\left(g_{1}(\mu(x))\right)\right)=\widehat{P}_{n / 2}\left(\left(\ell_{1} \mu(x)^{2}+\ell_{0}\right) q(x)^{2}\right) \tag{33}
\end{equation*}
$$

where $q(x) \equiv 1$. Thus, we arrived again at option (vi) with $\delta(x)=\mu(x)$ and $a=\ell_{1}, b=\ell_{0}$.

Now, if the standard pair $\left(f_{1}(x), g_{1}(x)\right)$ is of the third kind over $\mathbb{Q}$, then $\left(f_{1}(x), g_{1}(x)\right)=\left(D_{2}\left(x, \alpha^{t}\right), D_{t}\left(x, \alpha^{2}\right)\right)$ with $t$ being odd. Let us
substitute $f_{1}(x)=x^{2}-2 \alpha^{t}$ into (28) to deduce that $\ell(x)=\left(x+2 \alpha^{t}\right) / \lambda_{1}^{2}$, whence

$$
\begin{equation*}
g(x)=\widehat{P}_{n / 2}\left(\ell\left(g_{1}(\mu(x))\right)\right)=\widehat{P}_{n / 2}\left(\frac{D_{t}\left(\mu(x), \alpha^{2}\right)+2 \alpha^{t}}{\lambda_{1}^{2}}\right) . \tag{34}
\end{equation*}
$$

It follows from Proposition 2 that $-2 \alpha^{t} / \lambda_{1}^{2}$ is an extremum of the polynomial $D_{t}\left(\mu(x), \alpha^{2}\right) / \lambda_{1}^{2}$, which is of $P$-type $(1,2, \ldots, 2)$ as $t$ is odd. Hence $\left(D_{t}\left(\mu(x), \alpha^{2}\right)+2 \alpha^{t}\right) / \lambda_{1}^{2}=\delta(x) q(x)^{2}$ for some $\delta(x), q(x) \in \mathbb{Q}[x]$ with $\operatorname{deg} \delta(x)=1$. We deduce, that $g(x)$ is of the form (iv).

Finally, consider the case when $\left(f_{1}(x), g_{1}(x)\right)$ is a standard pair of the fourth kind over $\mathbb{Q}$. Then

$$
\left(f_{1}(x), g_{1}(x)\right)=\left(\frac{D_{2}(x, \alpha)}{\alpha}, \frac{D_{t}(x, \beta)}{\beta^{(t / 2)}}\right),
$$

with an even $t$. Substituting this into (28), an easy calculation yields $\ell(x)=(\alpha x+2 \alpha) / \lambda_{1}^{2}$, whence, by (25), we obtain

$$
\begin{equation*}
g(x)=\widehat{P}_{n / 2}\left(\ell\left(g_{1}(\mu(x))\right)\right)=\widehat{P}_{n / 2}\left(\frac{\alpha \beta^{-t / 2} D_{t}(\mu(x), \beta)+2 \alpha}{\lambda_{1}^{2}}\right) . \tag{35}
\end{equation*}
$$

Now from Proposition 2 we infer that

$$
-\frac{2 \beta^{t / 2} \alpha \beta^{-t / 2}}{\lambda_{1}^{2}}=-\frac{2 \alpha}{\lambda_{1}^{2}}
$$

is one of the two extrema of the polynomial $\alpha \beta^{-t / 2} D_{t}(\mu(x), \beta) /\left(\lambda_{1}^{2}\right)$ and it is of $P$-type $(2,2, \ldots, 2)$ as $t$ is even. Therefore we have

$$
\frac{\alpha \beta^{-t / 2} D_{t}(\mu(x), \beta)+2 \alpha}{\lambda_{1}^{2}}=q(x)^{2}
$$

for some $q(x) \in \mathbb{Q}[x]$. Thus $g(x)$ is of the form (iii), which completes the proof.
