**Exclusive J/ψ photoproduction off protons
in ultra-peripheral p–Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV**

ALICE Collaboration*

Abstract

We present the first measurement at the LHC of exclusive J/ψ photoproduction off protons, in ultra-peripheral proton-lead collisions at $\sqrt{s_{NN}} = 5.02$ TeV. Events are selected with a dimuon pair produced either in the rapidity interval, in the laboratory frame, $2.5 < y < 4$ (p–Pb) or $-3.6 < y < -2.6$ (Pb–p), and no other particles observed in the ALICE acceptance. The measured cross sections $\sigma(\gamma + p \rightarrow J/\psi + p)$ are 33.2 ± 2.2 (stat) ± 3.2 (syst) ± 0.7 (theo) nb in p–Pb and 284 ± 36 (stat) $^{+27}_{-32}$ (syst) ± 26 (theo) nb in Pb–p collisions. We measure this process up to about 700 GeV in the γp centre-of-mass, which is a factor of two larger than the highest energy studied at HERA. The data are consistent with a power law dependence of the J/ψ photoproduction cross section in γp energies from about 20 to 700 GeV, or equivalently, from Bjorken- x between $\sim 2 \times 10^{-2}$ to $\sim 2 \times 10^{-5}$, thus indicating no significant change in the gluon density behaviour of the proton between HERA and LHC energies.

arXiv:1406.7819v2 [nucl-ex] 14 Jul 2015

Exclusive J/ψ photoproduction off protons is defined by a reaction in which the J/ψ is produced from a γp interaction, where the proton emerges intact: $\gamma + p \rightarrow J/\psi + p$. This process allows a detailed study of the gluon distribution in the proton, since its cross section is expected to scale as the square of the gluon probability density function (PDF), according to leading order QCD calculations [1]. The mass of the charm quark provides an energy scale large enough to allow perturbative QCD calculations, albeit with some theoretical uncertainties [2]. This process provides a powerful tool to search for gluon saturation [3, 4], which is the most straightforward mechanism to slow down the growth of the PDF for gluons carrying a small fraction of the momentum of hadrons (Bjorken- x). Finding evidence of gluon saturation has become a central task for present experiments and for future projects [5, 6] that aim to study Quantum Chromo-Dynamics (QCD).

Both ZEUS and H1 measured the exclusive J/ψ photoproduction off protons at γp centre-of-mass energies ranging from 20 to 305 GeV [7, 8, 9]. This process has also been studied in pp [10], $p\bar{p}$ [11] and heavy-ion collisions [12, 13, 14].

In this Letter we present the first measurement of exclusive J/ψ photoproduction in collisions of protons with Pb nuclei at centre-of-mass energy per nucleon pair $\sqrt{s_{NN}} = 5.02$ TeV. The J/ψ is produced by the interaction of a photon with either a proton or a nuclear target, where the photon is emitted from one of the two colliding particles. Although both $\gamma + p \rightarrow J/\psi + p$ and $\gamma + \text{Pb} \rightarrow J/\psi + \text{Pb}$ can occur, the Pb electric charge makes the photon emission by ion to be strongly enhanced with respect to that from the proton [15, 16].

The main ALICE detector used in this analysis is the single-arm muon spectrometer [17], covering the pseudorapidity interval $-4.0 < \eta < -2.5$. The beam directions of the LHC were reversed in order to measure both forward and backward rapidity. Thus, J/ψ s are reconstructed in the $2.5 < y < 4.0$ (p–Pb) and $-3.6 < y < -2.6$ (Pb–p) rapidity intervals, where y is measured in the laboratory frame with respect to the proton beam direction¹. The γp centre-of-mass energy $W_{\gamma p}$ is determined by the J/ψ rapidity: $W_{\gamma p}^2 = 2E_p M_{J/\psi} \exp(-y)$, where $M_{J/\psi}$ is the J/ψ mass, y is the J/ψ rapidity and E_p is the proton energy ($E_p = 4$ TeV in the lab frame), while the Bjorken- x is given by $x = (M_{J/\psi}/W_{\gamma p})^2$. We study $21 < W_{\gamma p} < 45$ GeV for $y > 0$ and $577 < W_{\gamma p} < 952$ GeV for $y < 0$, thereby exceeding the γp range of HERA.

The muon spectrometer consists of a ten interaction length absorber, followed by five tracking stations, each made of two planes of cathode pad chambers, with the third station placed inside a dipole magnet with a 3 T·m integrated magnetic field. The muon trigger system, downstream of the tracking chambers, consists of four planes of resistive plate chambers placed behind a 7.2 interaction length iron wall. The single muon trigger threshold for the data used in this analysis was set to transverse momentum $p_T = 0.5$ GeV/ c . Other detectors used in this analysis are the Silicon Pixel Detector (SPD), VZERO and Zero Degree Calorimeters (ZDC) [17]. The central region $|\eta| < 1.4$ is covered by the SPD consisting of two cylindrical layers of silicon pixels. The pseudorapidity interval $2.8 < \eta < 5.1$ is covered by VZERO-A and $-3.7 < \eta < -1.7$ by VZERO-C. These detectors are scintillator tile arrays with a time resolution better than 1 ns, allowing us to distinguish between beam-beam and beam-gas interactions. The two ZDCs are located at ± 112.5 m from the interaction point, and are used to detect neutrons and protons emitted in the very forward region.

The trigger for the p–Pb configuration required two oppositely charged tracks in the muon spectrometer, and a veto on VZERO-A beam-beam interactions. In the Pb–p configuration, the trigger purity was improved with respect to the p–Pb by suppressing beam-induced backgrounds. This was achieved by requiring at least one hit in VZERO-C beam-beam trigger and a veto on VZERO-A beam-gas trigger. The integrated luminosity L was corrected for the probability that exclusivity requirements could be

¹The ALICE detector acceptance is given in the laboratory pseudorapidity η . The convention in ALICE is that the muon spectrometer is located at $\eta < 0$. In contrast, the laboratory rapidity y will change sign according to the proton beam direction, from which it takes its orientation. In p–Pb, for example, the proton goes in the $\eta < 0$ direction, and $y > 0$.

spoiled by multiple interactions in the same bunch crossing. This pile-up correction is on average 5%, giving $L = 3.9 \text{ nb}^{-1} \pm 3.7\%$ (syst) for p–Pb and $L = 4.5 \text{ nb}^{-1} \pm 3.4\%$ (syst) for Pb–p data [18].

Events with exactly two reconstructed tracks in the muon spectrometer were selected offline. The muon tracks had to fulfill the requirements on the radial coordinate of the track at the end of the absorber and on the extrapolation to the nominal vertex, as described in [12, 19]. Both track pseudorapidities were required to be within the chosen range $-4.0 < \eta_{\text{track}} < -2.5$ for p–Pb and $-3.7 < \eta_{\text{track}} < -2.5$ for Pb–p. Track segments in the tracking chambers must be matched with corresponding segments in the trigger chambers. The dimuon rapidity was in the range $2.5 < y < 4.0$ for p–Pb and $-3.6 < y < -2.6$ for Pb–p. The chosen range in Pb–p ensured that the muon tracks are in the overlap of the muon spectrometer and VZERO-C geometrical acceptance, as VZERO-C was part of the trigger in Pb–p. A cut on VZERO timing was imposed offline to be compatible with crossing beams. In order to reduce contamination from non-exclusive J/ψ s that come mainly from proton dissociation, only events with no mid-rapidity tracklets (track segments formed by two hits at each SPD layer) were kept. For the same reasons, events with neutron or proton activity in any of the ZDCs were rejected.

The dimuon invariant mass spectra ($M_{\mu^+\mu^-}$) after these selections are shown in Fig. 1. The J/ψ peak is clearly visible in both data sets, and is well described by a Crystal Ball parametrization [20], which yields masses and widths in agreement with the Monte Carlo simulations. The dimuon continuum is well described by an exponential as expected from two-photon production of continuum pairs ($\gamma\gamma \rightarrow \mu^+\mu^-$) [12, 13].

The extracted number of J/ψ s obtained from the invariant mass fit includes a mix of exclusive and non-exclusive J/ψ candidates. A different p_T distribution is expected from exclusive and non-exclusive J/ψ events [9]. For this reason, the number of exclusive J/ψ s can be determined from the dimuon p_T distributions shown in Fig. 2. The bulk of dimuon events having $p_T < 1 \text{ GeV}/c$ is mainly due to exclusive J/ψ production, while the tail extending up to higher p_T on the top panel (p–Pb) comes from non-exclusive interactions. Exclusive J/ψ coming from γp interactions and $\gamma\gamma$ contribute to both p_T spectra. In addition, for p–Pb, a background, coming from non-exclusive J/ψ s and non-exclusive $\gamma\gamma \rightarrow \mu^+\mu^-$ events was taken into account, while for the Pb–p sample a contribution from coherent J/ψ in γPb interactions was considered. The latter process was neglected in p–Pb as it amounts to less than 2% [16]. If modifications to the nuclear gluon distribution, also known as nuclear shadowing, are considered this contribution would be even smaller. Here, an additional 50% reduction is expected [13] from shadowing effects. The p_T shapes for the J/ψ in γp , $\gamma\gamma \rightarrow \mu^+\mu^-$, and coherent J/ψ in γPb components (Monte Carlo templates) were obtained using STARLIGHT [21, 22] events folded with the detector response simulation. For p–Pb, these templates were fitted to the data leaving the normalization free for J/ψ in γp and the non-exclusive background. The $\gamma\gamma \rightarrow \mu^+\mu^-$ component was constrained from the invariant mass fit shown in Fig. 1 [12]. The non-exclusive contributions were subtracted using this fitting procedure, giving $N_{J/\psi}$.

The p_T distribution of non-exclusive J/ψ candidates and the non-exclusive dimuon continuum were obtained from data, using the same event selection as above, but requiring events to have more than two hits in the VZERO-C counters. At HERA the ratio of the non-exclusive J/ψ production cross section to the exclusive one was found to decrease with $W_{\gamma p}$ [9]. Extrapolating, this means a factor 2 smaller non-exclusive J/ψ contribution in the Pb–p sample. We note that for this sample dissociation products went towards VZERO-A, used as veto at the trigger level, providing an explanation on the negligible non-exclusive contribution observed.

The number of exclusive J/ψ coming from γp interactions ($N_{J/\psi}^{\text{exc}}$) was obtained as $N_{J/\psi}^{\text{exc}} = N_{J/\psi}/(1 + f_D)$, where f_D is the fraction of J/ψ mesons coming from the decay of $\psi(2S)$. Following the procedure described in [12, 13], we obtained $f_D = 7.9_{-1.9}^{+2.4}\%$ (syst) in p–Pb and $f_D = 11_{-2.8}^{+3.6}\%$ (syst) in Pb–p. The contribution of exclusive χ_c states was neglected, as these are expected to be strongly suppressed in

Table 1: Summary of the contributions to the systematic uncertainty for the integrated J/ψ cross section measurement for the full rapidity intervals.

proton-nucleus collisions [23, 24]. The resulting yield is $N_{J/\psi}^{\text{exc}}(\text{p–Pb}) = 414 \pm 28$ (stat) ± 27 (syst).

$N_{J/\psi}^{\text{exc}}$ in the Pb–p sample was obtained by event counting, and then subtracting the $\gamma\gamma$ and the γPb components as well as the feed-down from $\psi(2\text{S})$ decays. Based on our recent coherent J/ψ results in γPb [12], taking into account the difference in the centre-of-mass energy, we estimated that 7 ± 2 (stat) events are expected in this sample. We obtained $N_{J/\psi}^{\text{exc}}(\text{Pb–p}) = 71 \pm 9$ (stat) $^{+2}_{-5}$ (syst). A compatible number for $N_{J/\psi}^{\text{exc}}$ was found studying the J/ψ p_T (see Fig. 2 bottom panel). The exclusive J/ψ template was obtained by changing the exponential slope of the p_T^2 spectrum in the Monte Carlo from its default value of 4.0 to 6.7 $(\text{GeV}/c)^{-2}$. This value agrees with an extrapolation of the $W_{\gamma p}$ dependence of the p_T^2 slope seen by H1 [9].

The product of the detector acceptance and efficiency $A \times \varepsilon$ for J/ψ was calculated using STARLIGHT and ranges from 11% to 31% for the rapidity intervals corresponding to the measurements given in Table 2. The systematic uncertainties on the measurement of the J/ψ cross section are listed in Table 1. The cross sections corresponding to exclusive J/ψ photoproduction off protons were obtained using $\frac{d\sigma}{dy} = \frac{N_{J/\psi}^{\text{exc}}}{(A \times \varepsilon) \cdot BR \cdot L \cdot \Delta y}$, where BR is the branching ratio and Δy is the rapidity interval. We obtained $\frac{d\sigma}{dy} = 6.42 \pm 0.43$ (stat) ± 0.61 (syst) μb for p–Pb and $\frac{d\sigma}{dy} = 2.46 \pm 0.31$ (stat) $^{+0.24}_{-0.28}$ (syst) μb for Pb–p collisions (see Table 2).

We measured the cross section for the exclusive $\gamma\gamma \rightarrow \mu^+ \mu^-$ process at invariant mass $1.5 < M_{\mu^+ \mu^-} < 2.5$ GeV/c^2 and in the rapidity range $2.5 < y < 4.0$, using the same technique as for the J/ψ to remove the non-exclusive background, obtaining $\sigma(\gamma\gamma \rightarrow \mu^+ \mu^-) = 1.76 \pm 0.12$ (stat) ± 0.16 (syst) μb for this kinematic range. The STARLIGHT prediction for this standard QED process is 1.8 μb , which is in good agreement with this measurement. This provides an additional indication that the non-exclusive background subtraction is under control.

The cross section $\frac{d\sigma}{dy}(\text{p} + \text{Pb} \rightarrow \text{p} + \text{Pb} + J/\psi)$ is related to the photon-proton cross section, $\sigma(\gamma + \text{p} \rightarrow J/\psi + \text{p}) \equiv \sigma(W_{\gamma p})$, through the photon flux, $\frac{dn}{dk}$:

$$\frac{d\sigma}{dy}(\text{p} + \text{Pb} \rightarrow \text{p} + \text{Pb} + J/\psi) = k \frac{dn}{dk} \sigma(\gamma + \text{p} \rightarrow J/\psi + \text{p}).$$

Here, k is the photon energy, which is determined by the J/ψ mass and rapidity, $k = (1/2)M_{J/\psi} \exp(-y)$. The average photon flux values for the different rapidity intervals were calculated using STARLIGHT

Rapidity	$\frac{d\sigma}{dy} (\mu b)$	$k \frac{d\sigma}{dk}$	$W_{\gamma p}$ (GeV)	$\langle W_{\gamma p} \rangle$ (GeV)	$\sigma(\gamma + p \rightarrow J/\psi + p)$ (nb)

Table 2: Differential cross sections for exclusive J/ψ photoproduction off protons in ultra-peripheral p–Pb and Pb–p collisions at $\sqrt{s_{NN}} = 5.02$ TeV. The corresponding J/ψ photoproduction cross sections in bins of $W_{\gamma p}$ are also presented.

and are listed in Table 2. The $\langle W_{\gamma p} \rangle$ is calculated by weighting with the product of the photon spectrum and the cross section $\sigma(\gamma p)$ from STARLIGHT. The photon spectrum is calculated in impact parameter space requiring that there should be no hadronic interaction. The uncertainty in this approach is estimated by increasing/decreasing the Pb-radius with ± 0.5 fm, corresponding to the nuclear skin thickness and of the same order as the upper limit for the difference between the proton and neutron radius of Pb when calculating the hadronic interaction probability. This gives an uncertainty of 9% in the photon flux for the high energy data point and 2% at low energy (see Table 2). The uncertainty is larger for the high photon energies since here one is dominated by small impact parameters and thus more sensitive to the rejection of hadronic interactions with impact parameters near the Pb radius.

Figure 3 shows the ALICE measurements for $\sigma(W_{\gamma p})$. Comparisons to previous measurements and to different theoretical models are also shown. As mentioned earlier, $\sigma(W_{\gamma p})$ is proportional to the square of the gluon PDF of the proton [1]. For HERA energies, the gluon distribution at low Bjorken- x is well described by a power law in x [26], which implies the cross section $\sigma(W_{\gamma p})$ will also follow a power law. A deviation from such a trend in the measured cross section as x decreases, or equivalently, as $W_{\gamma p}$ increases, could indicate a change in the evolution of the gluon density function, as expected at the onset of saturation.

Both ZEUS and H1 [7, 8, 9] fitted their data using a power law $\sigma \sim W_{\gamma p}^{\delta}$, obtaining $\delta = 0.69 \pm 0.02$ (stat) ± 0.03 (syst), and $\delta = 0.67 \pm 0.03$ (stat + syst), respectively. Due to the large HERA statistics, a simultaneous fit of H1, ZEUS, ALICE low energy points data gives power-law fit parameters almost identical to those obtained from HERA alone. A fit to ALICE data alone gives $\delta = 0.68 \pm 0.06$ (stat + syst), only uncorrelated systematic errors were considered here. Thus, no deviation from a power law is observed up to about 700 GeV.

Two calculations are available from the JMRT group [27]: the first one referred to as LO is based on a power law description of the process, while the second model is labeled as NLO, and includes contributions which mimic effects expected from the dominant NLO corrections. Because both JMRT models have been fitted to the same data, the resulting energy dependences are very similar. Our data support their extracted gluon distribution up to $x \sim 2 \times 10^{-5}$. The STARLIGHT parameterization is based on a power law fit using only fixed-target and HERA data, giving $\delta = 0.65 \pm 0.02$. Figure 3 also shows predictions from the b-Sat eikonalized model [28] which uses the Color Glass Condensate approach [29] to incorporate saturation, constraining it to HERA data alone. The results from the models mentioned above are within one sigma of our measurement. The b-Sat 1-Pomeron prediction taken from [5] also agrees with the ALICE low energy data points, but it is about 4 sigmas above our measurement at the highest energy.

LHCb recently published results for $\sigma(W_{\gamma p})$ based on exclusive J/ψ production in pp collisions [10]. Their analysis, using data from a symmetric system, suffers from the intrinsic impossibility of identifying the photon emitter and the photon target. Since the non-exclusive background, as mentioned above, depends on $W_{\gamma p}$, this feeds into the uncertainty in the subtraction of these processes, making the extraction of the underlying $\sigma(W_{\gamma p})$ to be strongly model dependent. Moreover, in contrast with p–Pb collisions, there is a large uncertainty in the hadronic survival probability in pp collisions, as well as an unknown

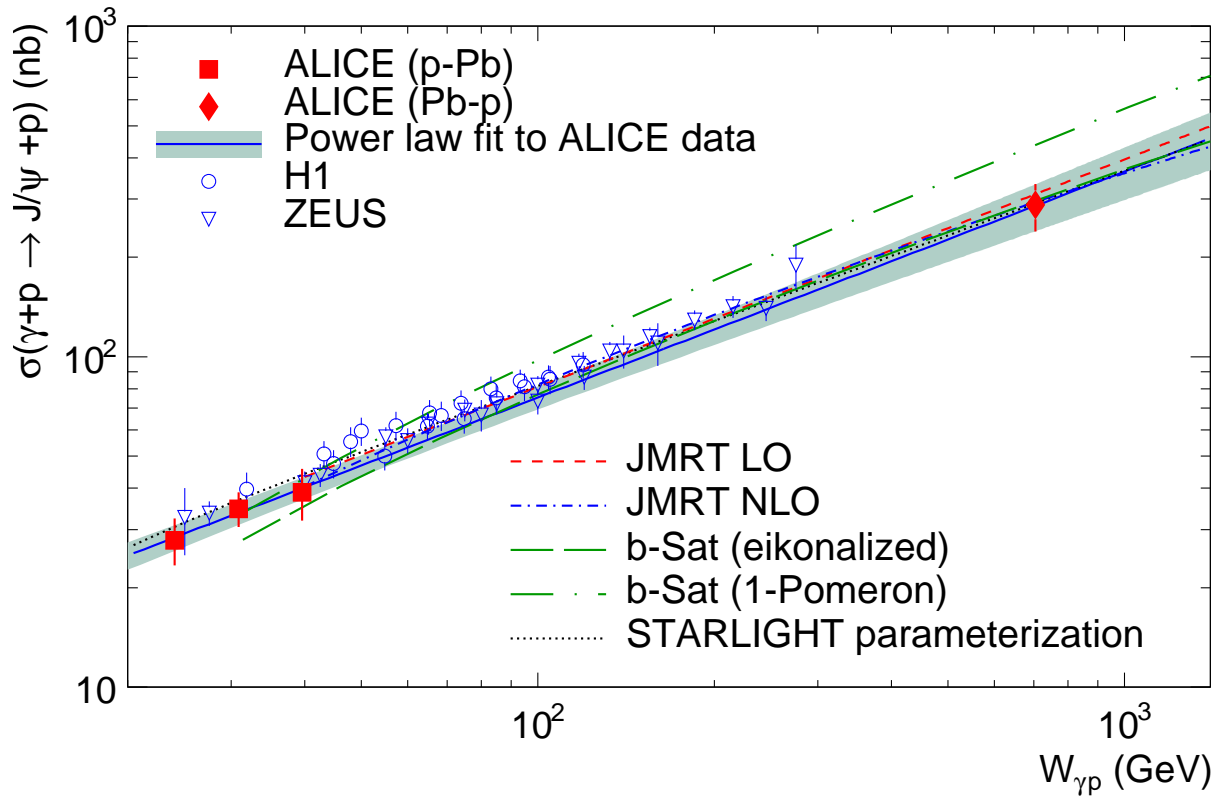

Fig. 3: Exclusive J/ψ photoproduction cross section off protons measured by ALICE and compared to HERA data. Comparisons to STARLIGHT, JMRT and the b-Sat models are shown. The power law fit to ALICE data is also shown.

contribution from production through Odderon-Pomeron fusion [11, 23]. For each $\frac{d\sigma}{dy}$ measurement, they reported a W_+ and a W_- solution. These coupled solutions are shown in Figure 4, together with the power law fit to ALICE measurements. Despite these ambiguities and assumptions the LHCb solutions turned out to be compatible with the power law dependence extracted from our data.

In summary, we have made the first measurement of exclusive J/ψ photoproduction off protons in p–Pb collisions at the LHC. Our data are compatible with a power law dependence of $\sigma(W_{\gamma p})$ up to about 700 GeV in $W_{\gamma p}$, corresponding to $x \sim 2 \times 10^{-5}$. A natural explanation is that no change in the behaviour of the gluon PDF in the proton is observed between HERA and LHC energies.

- ⁱⁱ Also at: St. Petersburg State Polytechnical University
- ⁱⁱⁱ Also at: Department of Applied Physics, Aligarh Muslim University, Aligarh, India
- ^{iv} Also at: M.V. Lomonosov Moscow State University, D.V. Skobeltsyn Institute of Nuclear Physics, Moscow, Russia
- ^v Also at: University of Belgrade, Faculty of Physics and "Vinča" Institute of Nuclear Sciences, Belgrade, Serbia
- ^{vi} Permanent Address: Permanent Address: Konkuk University, Seoul, Korea
- ^{vii} Also at: Institute of Theoretical Physics, University of Wrocław, Wrocław, Poland
- ^{viii} Also at: University of Kansas, Lawrence, KS, United States

Collaboration Institutes

- ¹ A.I. Alikhanyan National Science Laboratory (Yerevan Physics Institute) Foundation, Yerevan, Armenia
- ² Benemérita Universidad Autónoma de Puebla, Puebla, Mexico
- ³ Bogolyubov Institute for Theoretical Physics, Kiev, Ukraine
- ⁴ Bose Institute, Department of Physics and Centre for Astroparticle Physics and Space Science (CAPSS), Kolkata, India
- ⁵ Budker Institute for Nuclear Physics, Novosibirsk, Russia
- ⁶ California Polytechnic State University, San Luis Obispo, CA, United States
- ⁷ Central China Normal University, Wuhan, China
- ⁸ Centre de Calcul de l'IN2P3, Villeurbanne, France

- ⁹ Centro de Aplicaciones Tecnológicas y Desarrollo Nuclear (CEADEN), Havana, Cuba
- ¹⁰ Centro de Investigaciones Energéticas Medioambientales y Tecnológicas (CIEMAT), Madrid, Spain
- ¹¹ Centro de Investigación y de Estudios Avanzados (CINVESTAV), Mexico City and Mérida, Mexico
- ¹² Centro Fermi - Museo Storico della Fisica e Centro Studi e Ricerche “Enrico Fermi”, Rome, Italy
- ¹³ Chicago State University, Chicago, USA
- ¹⁴ Commissariat à l’Energie Atomique, IRFU, Saclay, France
- ¹⁵ COMSATS Institute of Information Technology (CIIT), Islamabad, Pakistan
- ¹⁶ Departamento de Física de Partículas and IGFAE, Universidad de Santiago de Compostela, Santiago de Compostela, Spain
- ¹⁷ Department of Physics and Technology, University of Bergen, Bergen, Norway
- ¹⁸ Department of Physics, Aligarh Muslim University, Aligarh, India
- ¹⁹ Department of Physics, Ohio State University, Columbus, OH, United States
- ²⁰ Department of Physics, Sejong University, Seoul, South Korea
- ²¹ Department of Physics, University of Oslo, Oslo, Norway
- ²² Dipartimento di Fisica dell’Università ‘La Sapienza’ and Sezione INFN Rome, Italy
- ²³ Dipartimento di Fisica dell’Università and Sezione INFN, Cagliari, Italy
- ²⁴ Dipartimento di Fisica dell’Università and Sezione INFN, Trieste, Italy
- ²⁵ Dipartimento di Fisica dell’Università and Sezione INFN, Turin, Italy
- ²⁶ Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Bologna, Italy
- ²⁷ Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Catania, Italy
- ²⁸ Dipartimento di Fisica e Astronomia dell’Università and Sezione INFN, Padova, Italy
- ²⁹ Dipartimento di Fisica ‘E.R. Caianiello’ dell’Università and Gruppo Collegato INFN, Salerno, Italy
- ³⁰ Dipartimento di Scienze e Innovazione Tecnologica dell’Università del Piemonte Orientale and Gruppo Collegato INFN, Alessandria, Italy
- ³¹ Dipartimento Interateneo di Fisica ‘M. Merlin’ and Sezione INFN, Bari, Italy
- ³² Division of Experimental High Energy Physics, University of Lund, Lund, Sweden
- ³³ Eberhard Karls Universität Tübingen, Tübingen, Germany
- ³⁴ European Organization for Nuclear Research (CERN), Geneva, Switzerland
- ³⁵ Faculty of Engineering, Bergen University College, Bergen, Norway
- ³⁶ Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovakia
- ³⁷ Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, Prague, Czech Republic
- ³⁸ Faculty of Science, P.J. Šafárik University, Košice, Slovakia
- ³⁹ Frankfurt Institute for Advanced Studies, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- ⁴⁰ Gangneung-Wonju National University, Gangneung, South Korea
- ⁴¹ Gauhati University, Department of Physics, Guwahati, India
- ⁴² Helsinki Institute of Physics (HIP), Helsinki, Finland
- ⁴³ Hiroshima University, Hiroshima, Japan
- ⁴⁴ Indian Institute of Technology Bombay (IIT), Mumbai, India
- ⁴⁵ Indian Institute of Technology Indore, Indore (IITI), India
- ⁴⁶ Inha University, Incheon, South Korea
- ⁴⁷ Institut de Physique Nucléaire d’Orsay (IPNO), Université Paris-Sud, CNRS-IN2P3, Orsay, France
- ⁴⁸ Institut für Informatik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- ⁴⁹ Institut für Kernphysik, Johann Wolfgang Goethe-Universität Frankfurt, Frankfurt, Germany
- ⁵⁰ Institut für Kernphysik, Westfälische Wilhelms-Universität Münster, Münster, Germany
- ⁵¹ Institut Pluridisciplinaire Hubert Curien (IPHC), Université de Strasbourg, CNRS-IN2P3, Strasbourg, France
- ⁵² Institute for Nuclear Research, Academy of Sciences, Moscow, Russia
- ⁵³ Institute for Subatomic Physics of Utrecht University, Utrecht, Netherlands
- ⁵⁴ Institute for Theoretical and Experimental Physics, Moscow, Russia
- ⁵⁵ Institute of Experimental Physics, Slovak Academy of Sciences, Košice, Slovakia
- ⁵⁶ Institute of Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic
- ⁵⁷ Institute of Physics, Bhubaneswar, India
- ⁵⁸ Institute of Space Science (ISS), Bucharest, Romania
- ⁵⁹ Instituto de Ciencias Nucleares, Universidad Nacional Autónoma de México, Mexico City, Mexico

- ⁶⁰ Instituto de Física, Universidad Nacional Autónoma de México, Mexico City, Mexico
⁶¹ iThemba LABS, National Research Foundation, Somerset West, South Africa
⁶² Joint Institute for Nuclear Research (JINR), Dubna, Russia
⁶³ Konkuk University, Seoul, South Korea
⁶⁴ Korea Institute of Science and Technology Information, Daejeon, South Korea
⁶⁵ KTO Karatay University, Konya, Turkey
⁶⁶ Laboratoire de Physique Corpusculaire (LPC), Clermont Université, Université Blaise Pascal, CNRS–IN2P3, Clermont-Ferrand, France
⁶⁷ Laboratoire de Physique Subatomique et de Cosmologie, Université Grenoble-Alpes, CNRS-IN2P3, Grenoble, France
⁶⁸ Laboratori Nazionali di Frascati, INFN, Frascati, Italy
⁶⁹ Laboratori Nazionali di Legnaro, INFN, Legnaro, Italy
⁷⁰ Lawrence Berkeley National Laboratory, Berkeley, CA, United States
⁷¹ Lawrence Livermore National Laboratory, Livermore, CA, United States
⁷² Moscow Engineering Physics Institute, Moscow, Russia
⁷³ National Centre for Nuclear Studies, Warsaw, Poland
⁷⁴ National Institute for Physics and Nuclear Engineering, Bucharest, Romania
⁷⁵ National Institute of Science Education and Research, Bhubaneswar, India
⁷⁶ Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark
⁷⁷ Nikhef, National Institute for Subatomic Physics, Amsterdam, Netherlands
⁷⁸ Nuclear Physics Group, STFC Daresbury Laboratory, Daresbury, United Kingdom
⁷⁹ Nuclear Physics Institute, Academy of Sciences of the Czech Republic, Řež u Prahy, Czech Republic
⁸⁰ Oak Ridge National Laboratory, Oak Ridge, TN, United States
⁸¹ Petersburg Nuclear Physics Institute, Gatchina, Russia
⁸² Physics Department, Creighton University, Omaha, NE, United States
⁸³ Physics Department, Panjab University, Chandigarh, India
⁸⁴ Physics Department, University of Athens, Athens, Greece
⁸⁵ Physics Department, University of Cape Town, Cape Town, South Africa
⁸⁶ Physics Department, University of Jammu, Jammu, India
⁸⁷ Physics Department, University of Rajasthan, Jaipur, India
⁸⁸ Physik Department, Technische Universität München, Munich, Germany
⁸⁹ Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany
⁹⁰ Politecnico di Torino, Turin, Italy
⁹¹ Purdue University, West Lafayette, IN, United States
⁹² Pusan National University, Pusan, South Korea
⁹³ Research Division and ExtreMe Matter Institute EMMI, GSI Helmholtzzentrum für Schwerionenforschung, Darmstadt, Germany
⁹⁴ Rudjer Bošković Institute, Zagreb, Croatia
⁹⁵ Russian Federal Nuclear Center (VNIIEF), Sarov, Russia
⁹⁶ Russian Research Centre Kurchatov Institute, Moscow, Russia
⁹⁷ Saha Institute of Nuclear Physics, Kolkata, India
⁹⁸ School of Physics and Astronomy, University of Birmingham, Birmingham, United Kingdom
⁹⁹ Sección Física, Departamento de Ciencias, Pontificia Universidad Católica del Perú, Lima, Peru
¹⁰⁰ Sezione INFN, Bari, Italy
¹⁰¹ Sezione INFN, Bologna, Italy
¹⁰² Sezione INFN, Cagliari, Italy
¹⁰³ Sezione INFN, Catania, Italy
¹⁰⁴ Sezione INFN, Padova, Italy
¹⁰⁵ Sezione INFN, Rome, Italy
¹⁰⁶ Sezione INFN, Trieste, Italy
¹⁰⁷ Sezione INFN, Turin, Italy
¹⁰⁸ SSC IHEP of NRC Kurchatov institute, Protvino, Russia
¹⁰⁹ SUBATECH, Ecole des Mines de Nantes, Université de Nantes, CNRS-IN2P3, Nantes, France
¹¹⁰ Suranaree University of Technology, Nakhon Ratchasima, Thailand
¹¹¹ Technical University of Split FESB, Split, Croatia
¹¹² The Henryk Niewodniczanski Institute of Nuclear Physics, Polish Academy of Sciences, Cracow, Poland

- 113 The University of Texas at Austin, Physics Department, Austin, TX, USA
- 114 Universidad Autónoma de Sinaloa, Culiacán, Mexico
- 115 Universidade de São Paulo (USP), São Paulo, Brazil
- 116 Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil
- 117 University of Houston, Houston, TX, United States
- 118 University of Jyväskylä, Jyväskylä, Finland
- 119 University of Liverpool, Liverpool, United Kingdom
- 120 University of Tennessee, Knoxville, TN, United States
- 121 University of Tokyo, Tokyo, Japan
- 122 University of Tsukuba, Tsukuba, Japan
- 123 University of Zagreb, Zagreb, Croatia
- 124 Université de Lyon, Université Lyon 1, CNRS/IN2P3, IPN-Lyon, Villeurbanne, France
- 125 V. Fock Institute for Physics, St. Petersburg State University, St. Petersburg, Russia
- 126 Variable Energy Cyclotron Centre, Kolkata, India
- 127 Vestfold University College, Tonsberg, Norway
- 128 Warsaw University of Technology, Warsaw, Poland
- 129 Wayne State University, Detroit, MI, United States
- 130 Wigner Research Centre for Physics, Hungarian Academy of Sciences, Budapest, Hungary
- 131 Yale University, New Haven, CT, United States
- 132 Yonsei University, Seoul, South Korea
- 133 Zentrum für Technologietransfer und Telekommunikation (ZTT), Fachhochschule Worms, Worms, Germany
