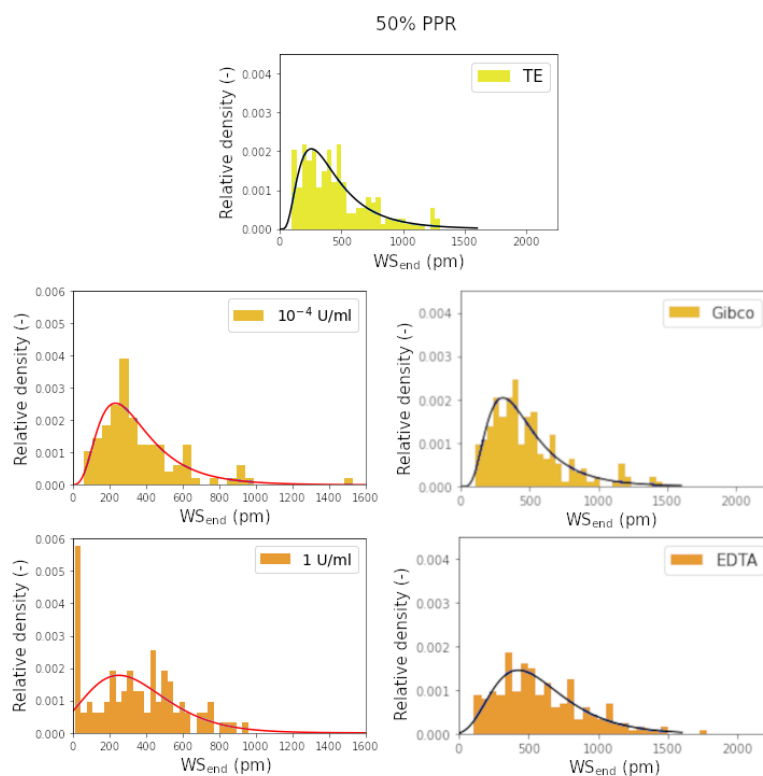

Figure S1. The adhesion signal distribution of HeLa fitted with lognormal distributions on 50% PPR-coated surface with glyocalyx digestion (ChrABC enzyme) and TE cell dissociation (first column) and with different cell dissociation methods (second column). The median and mean exhibit a monotonic decrease, while the standard deviation increases with higher enzyme concentration compared to lower enzyme concentration, resulting in a wider distribution. For Gibco and EDTA compared to TE, the effect on the distributions' median and mean are the opposite; they show an increase instead of a decrease. However, the impact on the standard deviation remains the same, the Gibco distribution has a smaller standard deviation than that

of the EDTA distribution. (It is important to note that TE was used in the glycocalyx digestion experiments.)

> 0.1	50 % PPR	Non-coated	Fibronectin
Gibco	31%	11%	11%
EDTA	45%	15%	13%
TE	39%	21%	15%

Table S1. The ratio of cells with a signal drop larger than 0.1 ($1-WS_{end}/WS_{max} > 0.1$) for the three cell dissociation methods on the three different surfaces.

> 0.2	50 % PPR	Non-coated	Fibronectin
Gibco	14%	1%	4%
EDTA	18%	3%	4%
TE	18%	3%	5%

Table S2. The ratio of cells with a signal drop larger than 0.2 ($1-WS_{end}/WS_{max} > 0.2$) for the three cell dissociation methods on the three different surfaces.

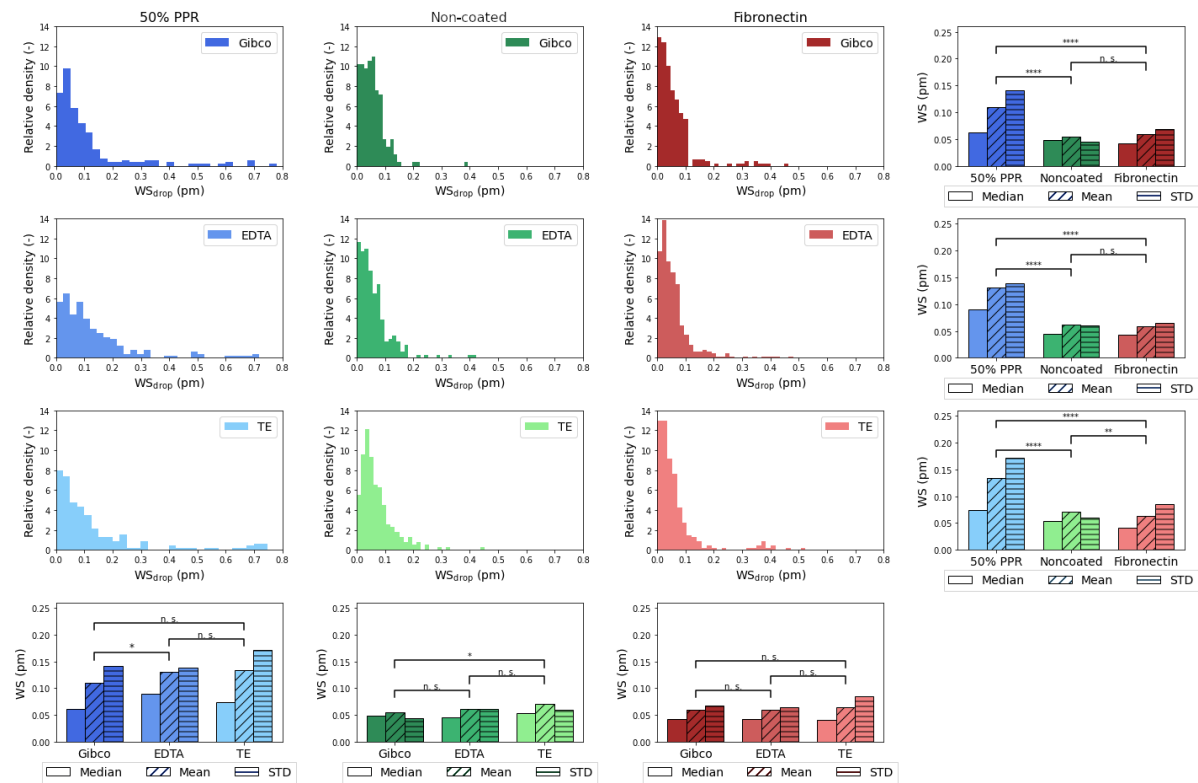

Figure S2. The sensor signal drop distribution of HeLa, on different surfaces (columns) and with different cell dissociation methods (rows). In the last row, the distributions of the different dissociation methods' median, mean, and standard deviation are depicted. In the last column, the median, mean, and standard deviation of the distributions of the different cell adhesion surfaces are shown. The significance analysis was carried out with a non-parametric Kruskal-

Wallis H-test test with Wilcoxon signed-rank test. $p < 0.05$: *, $p < 0.01$: **, $p < 0.001$: ***,
 $p < 0.0001$: ****
